PIECEWISE TENSOR PRODUCT WAVELET BASES BY EXTENSIONS AND APPROXIMATION RATES

NABI CHEGINI, STEPHAN DAHLKE, ULRICH FRIEDRICH, ROB STEVENSON

Abstract. Following [Studia Math., 76(2) (1983), pp. 1–58 and 95–136] by Z. Ciesielski and T. Figiel and [SIAM J. Math. Anal., 31 (1999), pp. 184–230] by W. Dahmen and R. Schneider, by the application of extension operators we construct a basis for a range of Sobolev spaces on a domain Ω from corresponding bases on subdomains that form a non-overlapping decomposition. As subdomains, we take hypercubes, or smooth parametric images of those, and equip them with tensor product wavelet bases. We prove approximation rates from the resulting piecewise tensor product basis that are independent of the spatial dimension of Ω. For two- and three dimensional polytopes we show that the solution of Poisson type problems satisfies the required regularity condition. The dimension independent rates will be realized numerically in linear complexity by the application of the adaptive wavelet-Galerkin scheme.

1. Introduction

Let \( \Omega = \bigcup_{k=0}^{N} \Omega_k \subset \mathbb{R}^n \) be a non-overlapping domain decomposition. By the use of extension operators, we will construct isomorphisms between the Cartesian product of Sobolev spaces on the subdomains, which incorporate suitable boundary conditions, and Sobolev spaces on \( \Omega \). By applying such an isomorphism to the union of Riesz bases for the Sobolev spaces on the subdomains, the result is a Riesz basis for the Sobolev space on \( \Omega \).

Since the approach can be applied recursively, to understand the construction of such an isomorphism, it is sufficient to consider the case of having two subdomains. For \( i \in \{1, 2\} \), let \( R_i \) be the restriction of functions on \( \Omega \) to \( \Omega_i \), let \( \eta_2 \) be the extension by zero of functions on \( \Omega_2 \) to functions on \( \Omega \), and let \( E_1 \) be some extension of functions on \( \Omega_1 \) to functions on \( \Omega \) which, for some \( m \in \mathbb{N}_0 \), is bounded from \( H^m(\Omega_1) \) to the target space \( H^m(\Omega) \). Then \( \begin{bmatrix} R_1 & R_2(\text{Id} - E_1 R_1) \end{bmatrix} : H^m(\Omega) \rightarrow H^m(\Omega_1) \times H^m_{0,\partial \Omega_1 \cap \partial \Omega_2}(\Omega_2) \) is boundedly invertible with inverse \( [E_1 \eta_2] \), see Figure 1 (\( H^m_{0,\partial \Omega_1 \cap \partial \Omega_2}(\Omega_2) \) is the space of \( H^m(\Omega_2) \) functions that vanish up to order \( m - 1 \) at \( \partial \Omega_1 \cap \partial \Omega_2 \)). Consequently, if \( \Psi_1 \) is a Riesz basis for \( H^m(\Omega_1) \) and \( \Psi_2 \) is a Riesz basis for \( H^m_{0,\partial \Omega_1 \cap \partial \Omega_2}(\Omega_2) \), then \( E_1 \Psi_1 \cup \eta_2 \Psi_2 \) is a Riesz basis for \( H^m(\Omega) \).

The principle to construct a basis for a function space on \( \Omega \) by applying an isomorphism between this space and the product of corresponding function spaces...
on non-overlapping subdomains was introduced in [CF83]. In [DS99] (see also [KS06]), this idea was revisited with the aim to practically construct such a basis for doing computations, rather than to show its existence.

In addition to the findings from [DS99], in the current work we derive precise conditions on the ordering of the subdomains so that the corresponding “true” extension operators (not the trivial zero extensions), being the building blocks of the isomorphism, actually do exist as bounded mappings. To explain this, as an example, consider the construction of a basis for $H^1(\Omega)$, where $\Omega$ is an L-shaped domain subdivided into 3 subdomains as illustrated in Figure 2. Choosing the action of the extension operators as illustrated by the subsequent arrows yields an invalid configuration, i.e., no bounded operators exist. Indeed, in view of the second extension from $\Omega_3$ to $\Omega$, in the first step we have to construct a Riesz basis for $H^1_{0,\partial\Omega_2\cap\partial\Omega_3}(\Omega_1 \cup \Omega_2)$, meaning that the first extension should be bounded from $H^1(\Omega_1)$ to $H^1_{0,\partial\Omega_2\cap\partial\Omega_3}(\Omega_1 \cup \Omega_2)$. In view of the boundary condition incorporated in the latter space, this is, however, impossible. On the other hand, by reversing one of the two arrows, one does obtain a valid configuration.

The conditions on the directions of the arrows will be different when homogeneous boundary conditions are imposed on the outer boundary, e.g., when a basis for $H^1_0(\Omega)$ is sought.

Our main interest in the construction of a basis from bases from subdomains lies in the use of piecewise tensor product approximation. On $\square$ one can construct a basis for the Sobolev space $H^m(\square)$ (or for a subspace incorporating Dirichlet boundary conditions) by taking an $n$-fold tensor product of a collection of univariate functions that forms a Riesz basis for $L^2(0,1)$ as well as, properly scaled, for $H^m(0,1)$. Thinking of a univariate wavelet basis of order $d > m$, the advantage of this approach is that the rate of nonlinear best $M$-term approximation of a sufficiently smooth function $u$ is $d - m$, compared to $\frac{d-m}{n}$ for standard best $M$-term isotropic
(wavelet) approximation of order $d$ on $\square$. The division of the “one-dimensional” rate $d - m$ by $n$ is commonly referred to as the curve of dimensionality.

One may argue that for any fixed $n$, a rate $d - m$ can also be obtained by isotropic approximation by increasing the order from $d$ to $nd - (n - 1)m$. Concerning the required smoothness of $u$, however, in the latter case it is (essentially) necessary and sufficient that for $1 \leq i \leq n$, $0 \leq k \leq m$, it holds that $\partial^\alpha \partial_i^k u \in L_p(\square)$ for $p = (d - m + \frac{1}{2})^{-1}$ and $|\alpha|_1 \leq n(d - m)$, whereas with tensor approximation the last condition reads as the much milder one $|\alpha|_\infty \leq d - m$ (cf. [Nit06, SU09] for details).

Actually, the above conditions guarantee only any rate $s < d - m$. Interpolation arguments that are used do not give a result for the “endpoint” $s = d - m$.

In any case, for dimensions $n \geq 3$, the solution of an elliptic boundary value problem of order $2m = 2$ generally does not satisfy the conditions such that isotropic approximation converges with the best, or any near best possible rate allowed by the polynomial order, i.e., $\frac{d - m}{n}$ for order $d$. In order to achieve this rate, generally anisotropic approximation is mandatory (cf. [Ape99]).

In addition to avoiding the curse of dimensionality, the possibility of anisotropic approximation is automatically included in (adaptive) tensor product approximation. In [DS10], see also [Nit05], it was shown that best approximations of $u$ from a suitably chosen nested sequence of spaces spanned by tensor product wavelets realizes the best possible rate $d - m$, so not only any near best possible rate, when for $1 \leq i \leq n$, $0 \leq k \leq m$ and $|\alpha|_\infty \leq d - m$, $\partial^\alpha \partial_i^k u$ is in a weighted $L_2(\square)$ space, with weight being an $n$-fold product of univariate weights on $(0, 1)$ that vanish near the endpoints. Clearly, the optimal rate $d - m$ for this linear approximation scheme implies this rate for the nonlinear best $M$-term approximation from the tensor product basis. What is more, in [DS10] it was shown that with a sufficiently smooth right-hand side, the solution of Poisson’s problem on the $n$-dimensional unit cube $\square$ satisfies this regularity condition.

In view of these results on $\square$, we consider a domain $\Omega$ whose closure is the union of $n$-cubes from $\mathbb{Z}^n + \square$, with $\square := (0, 1)^n$, or a domain $\Omega$ that is a parametric image of such a domain under a piecewise smooth, globally $C^{m-1}$ diffeomorphism $\kappa$. We equip $H^m(\Omega)$ (or a subspace incorporating Dirichlet boundary conditions) with a Riesz basis constructed from tensor product wavelet bases of order $d$ on the subdomains using extension operators as discussed before. Our restriction to decompositions of $\Omega$ into subdomains from a topological Cartesian grid will allow us to rely on univariate extensions. We will show the best possible approximation rate $d - m$ for any $u$ that is piecewise in the aforementioned weighted Sobolev spaces. The latter turns out to be technically hard. Indeed, in order to end up with locally supported wavelets, we will apply local, scale-dependent extension operators – i.e., only wavelets that are non-zero near an interface will be extended, – which do not preserve more smoothness than essentially membership of $H^m$.

Furthermore, using anisotropic regularity results recently shown in [CDN10], we show that if, additionally, $\Omega$ is a two- or, more interesting, a three-dimensional polytope, then for a sufficiently smooth right-hand side, the solution of Poisson’s problem satisfies this piecewise regularity condition. For that to hold in three dimensions, it will be needed that $\kappa$ is piecewise trilinear, and it may require a refinement of the initial decomposition of $\Omega$. 

Since it defines a boundedly invertible mapping from a Hilbert space, being $H^1_0(\Omega)$, to its dual, the Poisson problem is an example of a well-posed operator equation. Equipping $H^1_0(\Omega)$ with a Riesz basis constructed using extension operators from tensor product wavelet bases of order $d$ on the subdomains, the operator equation is equivalently formulated as a boundedly invertible bi-infinite matrix vector equation. Approximate solutions produced by the adaptive wavelet-Galerkin method ([CDD01, Ste09]) were proven to converge with the best possible rate in linear complexity. We perform numerical tests in two and three dimensions with wavelets of order $d = 5$ that confirm that this rate is $d - m$.

This paper is organized as follows: In Sect. 2, we present the abstract idea behind the construction of isomorphisms between Sobolev spaces on a domain and the product of corresponding Sobolev spaces on subdomains that form a non-overlapping decomposition.

In Sect. 3, we recall results on tensor product approximation on a hypercube, and collect assumptions on the univariate wavelets, being the building blocks of the tensor product wavelets.

In Sect. 4, we consider a domain $\Omega$ that is the union of hypercubes from a Cartesian grid of hypercubes. We formulate precise conditions on the order in which univariate extensions over interfaces are applied, and which boundary conditions have to be imposed, so that the composition of these extensions is an isomorphism between a range of Sobolev spaces on $\Omega$ and the product of the corresponding Sobolev spaces on the collection of hypercubes. Equipping these hypercubes with tensor product wavelet bases, we end up with a piecewise tensor product wavelet basis on $\Omega$.

In order to obtain locally supported primal and dual wavelets, in Sect. 5 the extension operators are replaced by scale-dependent modifications, in the sense that only wavelets with supports “near” the interfaces are extended. It is shown that approximation from the resulting piecewise tensor product basis gives rise to rates that are independent of the spatial dimension, assuming the function that is approximated satisfies some mild, piecewise weighted Sobolev smoothness conditions.

In Sect. 6, these regularity conditions are verified for the solution of Poisson’s problem with sufficiently smooth right-hand side in two and three-dimensional polytopes. The best possible rates from the piecewise tensor product basis can be realized in linear complexity by the application of the adaptive wavelet-Galerkin scheme. In Sect. 7, we present some numerical results obtained with this scheme.

2. Construction of the isomorphisms

In an abstract setting, for a class of mappings between a Banach space and the Cartesian product of two other Banach spaces, we give conditions on such mappings to be isomorphisms. The results will be applied to construct isomorphisms between a Sobolev space on a domain and the product of Sobolev spaces on subdomains.

**Proposition 2.1.** For normed linear spaces $V$ and $V_i$ ($i = 1, 2$), let $E_1 \in B(V_1, V)$, $\eta_2 \in B(V_2, V)$, $R_1 \in B(V, V_1)$, and $R_2 \in B(3\eta_2, V_2)$ be such that

\[ R_1 E_1 = \text{Id}, \quad R_2 \eta_2 = \text{Id}, \quad R_1 \eta_2 = 0, \quad \exists (\text{Id} - E_1 R_1) \subset 3\eta_2. \]

Then

\[ E = [E_1 \quad \eta_2] \in B(V_1 \times V_2, V) \text{ is boundedly invertible}, \]
with inverse

\[ E^{-1} = \begin{bmatrix} R_1 \\ R_2(\text{Id} - E_1R_1) \end{bmatrix}. \]

**Proof.** Using that \( R_1E_1 = \text{Id}, R_1\eta_2 = 0, R_2\eta_2 = \text{Id}, \) we have

\[ \begin{bmatrix} R_1 \\ R_2(\text{Id} - E_1R_1) \end{bmatrix} [E_1 \quad \eta_2] = \begin{bmatrix} \text{Id} & 0 \\ 0 & \text{Id} \end{bmatrix}, \]

and using that \( \Im(\text{Id} - E_1R_1) \subset \Im\eta_2 \) and \( R_2\eta_2 = \text{Id}, \) we have

\[ [E_1 \quad \eta_2] \begin{bmatrix} R_1 \\ R_2(\text{Id} - E_1R_1) \end{bmatrix} = E_1R_1 + \eta_2R_2(\text{Id} - E_1R_1) = \text{Id}. \]

□

In applications \( V \) (\( V_i \)) will be densely embedded in a Hilbert space \( H \) (\( H_i \)). Questions about boundedness of \( E \) or \( E^{-1} \) in dual spaces then reduce to properties of the Hilbert adjoint of \( E \). Study of the Hilbert adjoint will also be relevant for the investigation of dual bases.

**Proposition 2.2.** For Hilbert spaces \( H \) and \( H_i \) (\( i = 1, 2 \)), let \( R_i \in B(H,H_i) \), and isometries \( \eta_i \in B(H_i,H) \) be such that

\( R_i\eta_j = \delta_{ij} \quad (i,j \in \{1,2\}), \quad H = \Im\eta_1 \oplus \Im\eta_2, \)

and let \( E_1 \in B(H,H) \) be such that \( R_1E_1 = \text{Id} \).

Then \( \eta_1R_1 + \eta_2R_2 = \text{Id}, \quad E \in B(H_1 \times H_2,H) \) is boundedly invertible, \( \eta_i^* = R_i^* \), and

\[ E^* = \begin{bmatrix} E_1^* \\ R_2 \end{bmatrix}, \quad E^{-*} = [\eta_1 (\text{Id} - \eta_1E_1^*)\eta_2]. \]

**Proof.** The first statement follows from \( \eta_1R_1 + \eta_2R_2 = \text{Id} \) on \( \Im\eta_i \). The second statement follows from Proposition 2.1 once we have verified that \( \Im(\text{Id} - E_1R_1) \subset \Im\eta_2 \). Writing \( (\text{Id} - E_1R_1)x = \eta_1x + \eta_2x_2 \), and applying \( R_1 \) to both sides, we find \( x_1 = 0 \) as required. For any \( u \in H_i, \ v \in H, \)

\[ \langle \eta_1u, v \rangle_H = \langle \eta_1u, \sum_j \eta_jR_jv \rangle_H = \langle \eta_1u, \eta_1R_1v \rangle_H = \langle u, R_1v \rangle_H, \]

or \( \eta_i^* = R_i \). Now the last statement follows from the formulas for \( E \) and \( E^{-1} \) given in Proposition 2.1. □

**Remark 2.3.** The formulas for \( E \) and \( E^{-*} \), and so those for \( E^{-1} \) and \( E^* \) are symmetric, with reversed roles of \( H_i \) and \( H_2 \), in the sense that with \( E_2 := (\text{Id} - \eta_1E_1^*)\eta_2, \) it holds that \( (\text{Id} - \eta_2E_2^*)\eta_1 = E_1 \).

Let \( \tilde{V} \) and \( \tilde{V}_i \) (\( i = 1, 2 \)) be reflexive Banach spaces with

\[ \tilde{V} \hookrightarrow H, \quad \tilde{V}_i \hookrightarrow H_i \] with dense embeddings.

In this setting, we have that boundedness, or bounded invertibility of

\[ E : \tilde{V}_1' \times \tilde{V}_2' \rightarrow \tilde{V}' \]

is equivalent to boundedness, or to bounded invertibility of

\[ E^* : \tilde{V} \rightarrow \tilde{V}_1 \times \tilde{V}_2. \]
Proposition 2.4. Let the assumptions of Proposition 2.2 be valid. Let
\[ R_2 \in B(\tilde{V}, \tilde{V}_2), \quad \eta_1 \in B(\tilde{V}_1, \tilde{V}), \quad E_1^* \in B(\tilde{V}, \tilde{V}_1). \]
Then \( E^* \in B(\tilde{V}, \tilde{V}_1 \times \tilde{V}_2) \), and so \( E \in B(\tilde{V}_1', \tilde{V}_2', \tilde{V}') \), is boundedly invertible if and only if \( R_2 \) has a right-inverse \( \hat{E}_2 \in B(\tilde{V}_2, \tilde{V}) \).

Proof. The assumptions imply that \( E^* \in B(\tilde{V}, \tilde{V}_1 \times \tilde{V}_2) \), and that for \( E^{−s} \in B(\tilde{V}_1 \times \tilde{V}_2, \tilde{V}) \) it suffices to show that \( E_2 := (Id − \eta_1 E_1^*) \eta_2 \in B(\tilde{V}_2, \tilde{V}) \). If the latter is true, then, since \( R_2 E_2 = Id \), we can take \( \hat{E}_2 = E_2 \).

Conversely, let \( \hat{E}_2 \in B(\tilde{V}_2, \tilde{V}) \) be a right-inverse of \( R_2 \). We have that
\[ R_1 (Id − E_2 R_2) = R_1 − R_1 \eta_2 R_2 + R_1 \eta_1 E_1^* \eta_2 R_2 = R_1 + E_1^* \eta_2 R_2 \]
\[ = E_1^* (\eta_1 R_1 + \eta_2 R_2) = E_1^* \in B(\tilde{V}, \tilde{V}_1). \]
So
\[ \text{Id} − E_2 R_2 = (\eta_1 R_1 + \eta_2 R_2) (\text{Id} − E_2 R_2) = \eta_1 R_1 (\text{Id} − E_2 R_2) \in B(\tilde{V}, \tilde{V}), \]
or \( E_2 R_2 \in B(\tilde{V}, \tilde{V}) \). But then \( E_2 = E_2 R_2 \hat{E}_2 \in B(\tilde{V}_2, \tilde{V}) \).

Finally in this section, we apply interpolation arguments to conclude boundedness of \( E \) in scales of Banach spaces.

Proposition 2.5. (a) Let \( V, \tilde{V} \), and \( V_i, \tilde{V}_i \) \((i = 1, 2)\) be Banach spaces with
\[ V \hookrightarrow \tilde{V}, \quad V_i \hookrightarrow V_i \quad \text{with dense embeddings}. \]
Let the mappings \((R_1, R_2, E_1, \eta_2)\) satisfy the conditions from Proposition 2.1 for both triples \((V, V_1, V_2)\) and \((\tilde{V}, \tilde{V}_1, \tilde{V}_2)\). Then for \( s \in [0, 1], q \in [1, \infty] \),
\[ E \in B([V_1, \tilde{V}_1]_{s,q} \times [V_2, \tilde{V}_2]_{s,q}, [V, \tilde{V}]_{s,q}) \] is boundedly invertible.

(b) Let \( \tilde{V}, \tilde{V}_i \), and \( \tilde{V}_i, \tilde{V}_i \) be reflexive Banach spaces, and \( H \) and \( H_i \) be Hilbert spaces \((i = 1, 2)\) with
\[ \tilde{V} \hookrightarrow \tilde{H}, \quad \tilde{V}_i \hookrightarrow \tilde{H}_i \quad \text{with dense embeddings}. \]
Let the conditions of Proposition 2.2 be satisfied, as well as the conditions of Proposition 2.4 for both triples \((\tilde{V}, \tilde{V}_1, \tilde{V}_2)\) and \((\tilde{V}, \tilde{V}_1, \tilde{V}_2)\). Then for \( s \in [0, 1], q \in [1, \infty] \),
\[ E \in B([\tilde{V}_1, \tilde{V}_1]_{s,q} \times [\tilde{V}_2, \tilde{V}_2]_{s,q}, [\tilde{V}, \tilde{V}]_{s,q}) \] is boundedly invertible.

3. Approximation by Tensor Product Wavelets on the Hypercube

We will study non-overlapping domain decompositions, where the subdomains are either unit cubes or smooth images of those. Sobolev spaces on these cubes, that appear with the construction of a Riesz basis for a Sobolev space on the domain as a whole, will be equipped with tensor product wavelet bases. From [DS10], we recall the construction of those bases, as well as results on the rate of approximation from spans of suitably chosen subsets of these bases.

For \( t \in [0, \infty) \setminus (\mathbb{N}_0 + \{ \frac{1}{2} \}) \) and \( \bar{\sigma} = (\sigma_l, \sigma_r) \in \{0, \ldots, |t + \frac{1}{2}|\}^2 \), with \( \mathcal{I} := (0, 1) \), let
\[ H^l_{\bar{\sigma}}(\mathcal{I}) := \{ v \in H^l(\mathcal{I}) : v(0) = \cdots = v((\sigma_r−1)(0)) = 0 = v(1) = \cdots = v((\sigma_r−1)(1)) \}. \]

Remark 3.1. Later, we will use this definition also with \( \mathcal{I} \) reading as a general non-empty interval, with 0 and 1 reading as its left and right boundary.
For \( t \) and \( \tilde{\sigma} \) as above, and for \( \tilde{t} \in [0, \infty) \setminus (\mathbb{N}_0 + \{ \frac{1}{2} \}) \) and \( \tilde{\sigma} = (\tilde{\sigma}_t, \tilde{\sigma}_r) \in \{0, \ldots, [\tilde{t} + \frac{1}{2}]\}^2 \), we assume \textit{univariate wavelet} collections

\[
\Psi_{\tilde{\sigma}, \tilde{\beta}} := \left\{ \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})} : \lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}} \right\} \subset H^1_{\tilde{\beta}}(I)
\]

such that

\((W_1)\) \( \Psi_{\tilde{\sigma}, \tilde{\beta}} \) is a Riesz basis for \( L_2(I) \),

\((W_2)\) \( \left\{ 2^{-|\lambda|} \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})} : \lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}} \right\} \) is a Riesz basis for \( H^1_{\tilde{\beta}}(I) \),

where \( |\lambda| \in \mathbb{N}_0 \) denotes the \textit{level} of \( \lambda \). Denoting the dual basis of \( \Psi_{\tilde{\sigma}, \tilde{\beta}} \) for \( L_2(I) \) as

\[
\tilde{\Psi}_{\tilde{\sigma}, \tilde{\beta}} := \left\{ \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})} : \lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}} \right\},
\]

furthermore we assume that

\((W_3)\) \( \left\{ 2^{-|\lambda|} \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})} : \lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}} \right\} \) is a Riesz basis for \( H^1_{\tilde{\beta}}(I) \),

and that for some

\[
N \ni d > t,
\]

\((W_4)\) \( \| \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta}), u} \|_{L_2(I)} \leq 2^{-|\lambda|} \| u \|_{H^d(\supp \tilde{\psi}^{(\tilde{\sigma}, \tilde{\beta})})} (u \in H^d(I) \cap H^1_{\tilde{\beta}}(I)),
\]

\((W_5)\) \( \rho := \sup_{\lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}}} 2^{-|\lambda|} \max(\text{diam supp } \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})}, \text{diam supp } \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})}) \)

\[
\approx \inf_{\lambda \in \nabla_{\tilde{\sigma}, \tilde{\beta}}} 2^{-|\lambda|} \max(\text{diam supp } \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})}, \text{diam supp } \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})}),
\]

\((W_6)\) \( \sup_{j,k \in \mathbb{N}_0} \#(\{ |\lambda| = j : [k2^{-j}, (k + 1)2^{-j}] \cap (\text{supp } \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})} \cup \text{supp } \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\beta})}) \neq \emptyset \} < \infty.
\]

The conditions \((W_5)\) and \((W_6)\) will be referred to by saying that \textit{both primal and dual wavelets} are \textit{local} or \textit{locally finite}, respectively. For some arguments, it will be used that by increasing the coarsest scale, the constant \( \rho \) can always be assumed to be sufficiently small.

With, for \( n \in \mathbb{N} \),

\[
\square := I^n,
\]

one has \( L_2(\square) = \bigotimes_{i=1}^n L_2(I) \). For

\[
\sigma = (\sigma_t, ((\sigma_1)_t, (\sigma_1)_r))_{1 \leq i \leq n} \in \{0, \ldots, [t + \frac{1}{2}]\}^2,
\]

we define

\[
H^1_{\sigma}(\square) := H^1_{\sigma_t}(I) \otimes L_2(\square) \otimes \cdots \otimes L_2(\square) \otimes \cdots \otimes L_2(\square) \otimes \cdots \otimes L_2(\square) \otimes H^1_{\sigma_r}(I),
\]

which is the space of \( H^1(\square) \)-functions whose normal derivatives of up to orders \( (\sigma_1)_t \) and \( (\sigma_1)_r \) vanish at the facets \( \overline{I}^{n-1} \times \{0\} \times \overline{I}^{n-2} \) and \( \overline{I}^{n-1} \times \{1\} \times \overline{I}^{n-2} \), respectively \((1 \leq i \leq n) \) (the proof of this fact given in [DS10] for \( t \in \mathbb{N}_0 \) can be generalized to \( t \in [0, \infty) \setminus (\mathbb{N}_0 + \frac{1}{2}) \)).

The \textit{tensor product wavelet} collection

\[
\Psi_{\sigma, \tilde{\beta}} := \bigotimes_{i=1}^n \Psi_{\sigma_t, \tilde{\beta}_t} = \left\{ \psi_{\lambda}^{(\sigma, \tilde{\beta})} := \bigotimes_{i=1}^n \psi_{\lambda_i}^{(\sigma_t, \tilde{\beta}_t)} : \lambda \in \nabla_{\sigma, \tilde{\beta}} := \prod_{i=1}^n \nabla_{\sigma_t, \tilde{\beta}_t} \right\},
\]

and its renormalized version \( \{ \left( \sum_{i=1}^n 4^{|\lambda_i|} \right)^{-1/2} \psi_{\lambda}^{(\sigma, \tilde{\beta})} : \lambda \in \nabla_{\sigma, \tilde{\beta}} \} \) are Riesz bases for \( L_2(\square) \) and \( H^1_{\sigma}(\square) \), respectively. The collection that is dual to \( \Psi_{\sigma, \tilde{\beta}} \) reads as

\[
\tilde{\Psi}_{\sigma, \tilde{\beta}} := \bigotimes_{i=1}^n \tilde{\Psi}_{\sigma_t, \tilde{\beta}_t} = \left\{ \tilde{\psi}_{\lambda}^{(\sigma, \tilde{\beta})} := \bigotimes_{i=1}^n \tilde{\psi}_{\lambda_i}^{(\sigma_t, \tilde{\beta}_t)} : \lambda \in \nabla_{\sigma, \tilde{\beta}} \right\},
\]

and its renormalized version \( \{ \left( \sum_{i=1}^n 4^{|\lambda_i|} \right)^{-1/2} \tilde{\psi}_{\lambda}^{(\sigma, \tilde{\beta})} : \lambda \in \nabla_{\sigma, \tilde{\beta}} \} \) is a Riesz basis for \( H^1_{\sigma}(\square) \).
For \( \lambda \in \nabla_{\sigma, \hat{\sigma}} \), we set \(|\lambda| := (|\lambda_1|, \ldots, |\lambda_n|)\). As usual, for \( j, \hat{j} \in \mathbb{N}_0^n \), \(|j| \leq |\hat{j}|\) will mean that \(|j_i| \leq |\hat{j}_i|\) (\(1 \leq i \leq n\)), whereas \(|\hat{j}| \geq |j|\) or \(|\hat{j}| = |j|\) will mean that \(|\hat{j}| \leq |j|\) or \(|\hat{j}| \leq |j|\) and \(|\hat{j}| \geq |j|\), respectively.

For \( \theta \geq 0 \), the weighted Sobolev space \( \mathcal{H}^d_{m, \theta}(\mathcal{I}) \) is defined as the space of all measurable functions \( u \) on \( \mathcal{I} \) for which the norm

\[
\|u\|_{\mathcal{H}^d_{m, \theta}(\mathcal{I})} := \left[ \sum_{j=0}^{d} \int_{\mathcal{I}} |x^\theta(1-x)^{\theta} u(x)|^2 dx \right]^{\frac{1}{2}}
\]

is finite. For \( m \in \{0, \ldots, [\ell]\} \), we will consider the weighted Sobolev space

\[
\mathcal{H}^d_{m, \theta}(\Box) := \cap_{p=1}^{n} \cap_{i=1}^{n} \mathcal{H}^d_{\theta - \delta_p \min(m, \theta)}(\mathcal{I}),
\]
equipped with a squared norm that is the sum over \( p = 1, \ldots, n \) of the squared norms on \( \cap_{i=1}^{n} \mathcal{H}^d_{\theta - \delta_p \min(m, \theta)}(\mathcal{I}) \).

**Theorem 3.2** ([DS10, Thm. 4.3]). For any \( \theta \in [0, d] \), there exist a (nested) sequence \( (\nabla_{M}^{(\sigma, \hat{\sigma})})_{M \in \mathcal{N}} \subset \nabla_{\sigma, \hat{\sigma}} \) with \( \#\nabla_{M}^{(\sigma, \hat{\sigma})} \asymp M \), such that

\[
\inf_{v \in \text{span}(\psi_{M}^{(\sigma, \hat{\sigma})}, \lambda \in \nabla_{M}^{(\sigma, \hat{\sigma})})} \|u-v\|_{H^m(\Box)} \leq M^{-(d-m)} \|u\|_{\mathcal{H}^d_{m, \theta}(\Box)}, \quad (u \in \mathcal{H}^d_{m, \theta}(\Box) \cap H^m_{\sigma}(\Box)),
\]

where for \( m = 0 \), \( M^{-(d-m)} \) should be read as \((\log M)^{(n-1)(\frac{1}{2} + \theta)} M^{-d}\).

The index sets \( \nabla_{M}^{(\sigma, \hat{\sigma})} \) can be chosen to have the following multiple tree property:

For any \( \lambda \in \nabla_{M}^{(\sigma, \hat{\sigma})} \) and any \( j \in \mathbb{N}_0^n \) with \( j \leq |\lambda| \), there exists a \( \mu \in \nabla_{M}^{(\sigma, \hat{\sigma})} \) with \(|\mu| = j \), and \( \text{supp} \psi_{\mu}^{(\sigma, \hat{\sigma})} \cap \text{supp} \psi_{\lambda}^{(\sigma, \hat{\sigma})} \neq \emptyset \).

With the notations \( u \in H^{1}_\sigma(\alpha + \Box) \) and \( u \in H^{d}_{m, \theta}(\alpha + \Box) \), we will mean that \( u(\cdot + \alpha) \in H^{1}_{\sigma}(\Box) \) or \( u(\cdot + \alpha) \in H^{d}_{m, \theta}(\Box) \), respectively.

4. Construction of Riesz bases by extension

Let \( \{\Box_0, \ldots, \Box_N\} \) be a set of hypercubes in \( \mathbb{Z}^n + \Box \), and let \( \hat{\Omega} \) be a (reference) domain (i.e., open and connected) in \( \mathbb{R}^n \) with \( \cup_{k=0}^{N} \Box_k = \Omega \subset \cup_{k=0}^{N} \Box_k \cap \text{int} \), and such that \( \partial \hat{\Omega} \) is the union of (closed) facets of the \( \Box_k \)’s. The case \( \Omega \subset \cup_{k=0}^{N} \Box_k \cap \text{int} \) corresponds to the situation that \( \hat{\Omega} \) has one or more cracks. We will describe a construction of Riesz bases for Sobolev spaces on \( \hat{\Omega} \) from Riesz bases for corresponding Sobolev spaces on the subdomains \( \Box_k \) using extension operators. We start with giving sufficient conditions \((D_1)-(D_5)\) such that suitable extension operators exist. At the end of this section, we will consider domains given as the parametric image of \( \hat{\Omega} \).

We assume that there exists a sequence \( \{(\hat{\Omega}_k^{(q)} : q \leq k \leq N)\}_{0 \leq q \leq N} \) of sets of polytopes, such that \( \hat{\Omega}_k^{(0)} = \Box_k \) and where each next term in the sequence is created from its predecessor by joining two of its polytopes. More precisely, we assume that for any \( 1 \leq q \leq N \), there exists a \( q \leq k = k(q) \leq N \) and \( q-1 \leq k_1 = k_1(q) \neq k_2 = k_2(q) \leq N \) such that

\[
(D_1) \quad \hat{\Omega}_k^{(q)} = \left( \hat{\Omega}_{k_1}^{(q-1)} \cup \hat{\Omega}_{k_2}^{(q-1)} \setminus \partial \hat{\Omega}_k^{(q-1)} \right) \cap \text{int} \quad \text{is connected, and the interface } J := \hat{\Omega}_k^{(q)} \setminus (\hat{\Omega}_{k_1}^{(q-1)} \cup \hat{\Omega}_{k_2}^{(q-1)}) \text{ is part of a hyperplane},
\]
(D₂) \( \{ \Omega_k^{(q)} : q \leq k \leq N, k \neq \bar{k} \} = \{ \Omega_k^{(q-1)} : q - 1 \leq k \leq N, k \neq \{k_1, k_2\} \} \),

(\( D₃ \)) \( \Omega_N^{(N)} = \hat{\Omega} \).

For some \( t \in [0, \infty) \setminus (N_0 + \{ \frac{1}{2} \}) \),
to each of the closed facets of all the hypercubes \( \square_k \), we associate a number in \( \{0, \ldots, \lceil t + \frac{1}{2} \rceil \} \) indicating the order of the Dirichlet boundary condition on that facet (where a Dirichlet boundary condition of order 0 means no boundary condition). On facets on the boundary of \( \Omega \), this number can be chosen at one’s convenience (it is dictated by the boundary conditions of the boundary value problem that one wants to solve on \( \Omega \)), and, as will follow from the conditions imposed below, on the other facets it should be either 0 or \( \lceil t + \frac{1}{2} \rceil \).

By construction, each facet of any \( \hat{\Omega}_k^{(q)} \) is a union of some facets of the \( \square_k \)'s, that will be referred to as subfacets. Letting each of these subfacets inherit the Dirichlet boundary conditions imposed on the \( \square_k \)'s, we define

\[ \hat{\mathcal{H}}^t(\hat{\Omega}_k^{(q)}), \]

and so for \( k = q = N \) in particular \( \hat{\mathcal{H}}^t(\hat{\Omega}) = \hat{\mathcal{H}}^t(\hat{\Omega}_N^{(N)}) \), to be the closure in \( \mathcal{H}^t(\hat{\Omega}_k^{(q)}) \) of the smooth functions on \( \hat{\Omega}_k^{(q)} \) that satisfy these boundary conditions. Note that for \( 0 \leq k \leq N \), for some \( \sigma(k) \in (\{0, \ldots, \lceil t + \frac{1}{2} \rceil\})^n \),

\[ \hat{\mathcal{H}}^t(\hat{\Omega}_k^{(0)}) = \hat{\mathcal{H}}^t(\square_k) = \mathcal{H}^t_{\sigma(k)}(\square_k). \]

**Remark 4.1.** On the intersection of facets of hypercubes \( \square_k \), the natural interpretation of the boundary conditions is the minimal one such that the boundary conditions on each of these facets is not violated.

The boundary conditions on the hypercubes that determine the spaces \( \hat{\mathcal{H}}^t(\hat{\Omega}_k^{(q)}) \), and the order in which polytopes are joined should be chosen such that

(\( D₄ \)) on the \( \hat{\Omega}_k^{(q-1)} \) and \( \hat{\Omega}_k^{(q-1)} \) sides of \( J \), the boundary conditions are of order 0 and \( \lceil t + \frac{1}{2} \rceil \), respectively,

and, w.l.o.g. assuming that \( J = \{0\} \times \bar{J} \) and \( (0, 1) \times \bar{J} \subset \Omega_k^{(q-1)} \),

(\( D₅ \)) for any function in \( \hat{\mathcal{H}}^t(\hat{\Omega}_k^{(q-1)}) \) that vanishes near \( (0, 1) \times \bar{J} \), its reflection in \( \{0\} \times \mathbb{R}^{n-1} \) (extended with zero, and then restricted to \( \hat{\Omega}_k^{(q-1)} \)) is in \( \hat{\mathcal{H}}^t(\hat{\Omega}_k^{(q-1)}) \).

The condition (\( D₅ \)) can be formulated by saying that the order of the boundary condition at any subfacet of \( \hat{\Omega}_k^{(q-1)} \) adjacent to \( J \) should not be less than this order at its reflection in \( J \), where in case this reflection is not part of \( \partial \hat{\Omega}_k^{(q-1)} \) the latter order should be read as the highest possible one \( \lceil t + \frac{1}{2} \rceil \); and furthermore, that the order of the boundary condition at any subfacet of \( \hat{\Omega}_k^{(q-1)} \) adjacent to \( J \) should not be larger than this order at its reflection in \( J \), where in case this reflection is not part of \( \partial \hat{\Omega}_k^{(q-1)} \), the latter order should be read as the lowest possible one 0. See Figure 3 for an illustration.

Given \( 1 \leq q \leq N \), for \( i \in \{1, 2\} \), let \( R_i^{(q)} \) be the restriction of functions on \( \hat{\Omega}_k^{(q)} \) to \( \hat{\Omega}_k^{(q-1)} \), let \( \eta_2^{(q)} \) be the extension of functions on \( \hat{\Omega}_k^{(q-1)} \) to \( \hat{\Omega}_k^{(q)} \) by zero, and let \( E_1^{(q)} \) be some extension of functions on \( \hat{\Omega}_k^{(q-1)} \) to \( \hat{\Omega}_k^{(q)} \).
Assume that $W.l.o.g.$ let

$$E = \begin{cases} \hat{\Omega}^{(q-1)}_{k_2} & \text{order } i \leq \text{order } j \\ \hat{\Omega}^{(q-1)}_{k_2} & \text{order } |t + \frac{1}{2}| \end{cases}$$

$\bar{\Omega}^{(q-1)}_{k_2}$

order 0

order $|t + \frac{1}{2}|$

order $i \leq \text{order } j$

$\bar{\Omega}^{(q-1)}_{k_2}$

$\Omega^{(q-1)}_{k_2}$

$\Omega^{(q-1)}_{k_2}$

Figure 3. Two illustrations with $(\mathcal{D}_1)$–$(\mathcal{D}_3)$. The fat arrow indicates the action of the extension $E_1^{(q)}$.

**Proposition 4.2.** Assume that

$$E_1^{(q)} \in B(L_2(\hat{\Omega}^{(q-1)}_{k_1}), L_2(\hat{\Omega}^{(q)}_{k})),$$  

then for $s \in [0, 1]$

$$E^{(q)} := [E_1^{(q)}, \eta_2^{(q)}] \in B(\bigcup_{i=1}^2 [L_2(\hat{\Omega}^{(q-1)}_{k_i}), \hat{H}^t(\hat{\Omega}^{(q)}_{k})], [L_2(\hat{\Omega}^{(q)}_{k}), \hat{H}^t(\hat{\Omega}^{(q)}_{k})], [L_2(\hat{\Omega}^{(q-1)}_{k}), \hat{H}^t(\hat{\Omega}^{(q-1)}_{k})], [L_2(\hat{\Omega}^{(q-1)}_{k}), \hat{H}^t(\hat{\Omega}^{(q-1)}_{k})])$$

is boundedly invertible.

**Proof.** Taking $V^{(q)} = L_2(\hat{\Omega}^{(q)}_{k})$, $V_q^{(q)} = L_2(\hat{\Omega}^{(q-1)}_{k})$, $V_i^{(q)} = \hat{H}^t(\hat{\Omega}^{(q)}_{k})$, $V_i^{(q)} = \hat{H}^t(\hat{\Omega}^{(q-1)}_{k})$, and noting that $\Im(Id - E_1^{(q)}R_1^{(q)}) \subset \{ u \in \hat{H}^t(\hat{\Omega}^{(q)}_{k}) : u = 0 \text{ on } \hat{\Omega}^{(q-1)}_{k} \} = \Im(\eta_2^{(q)}|_{\hat{H}^t(\hat{\Omega}^{(q-1)}_{k})})$, the result follows from an application of Proposition 2.5(a). \( \square \)

**Corollary 4.3.** For $E$ being the composition for $q = 1, \ldots, N$ of the mappings $E^{(q)}$ from Proposition 4.2, trivially extended with identity operators in coordinates $k \in \{ q - 1, \ldots, N \} \setminus \{ k_1^{(q)}, k_2^{(q)} \}$, it holds that

$$E \in B \left( \prod_{k=0}^n [L_2(\hat{\Omega}^{(q-1)}_{k}), \hat{H}^t(\hat{\Omega}^{(q-1)}_{k})], [L_2(\hat{\Omega}^{(q-1)}_{k}), \hat{H}^t(\hat{\Omega}^{(q-1)}_{k})]) \right).$$

is boundedly invertible.

Under the conditions $(\mathcal{D}_1)$–$(\mathcal{D}_3)$, the extensions $E_1^{(q)}$ can be constructed (essentially) as tensor products of univariate extensions with identity operators in the other Cartesian directions.

**Proposition 4.4.** W.l.o.g. let $J = \{0\} \times \hat{J}$ and $(0, 1) \times \hat{J} \subset \hat{\Omega}^{(q-1)}_{k_1}$. Let $G_1$ be an extension operator of functions on $(0, 1)$ to functions on $(-1, 1)$ such that

$$G_1 \in B(L_2(0, 1), L_2(-1, 1)), \quad G_1 \in B(H^t(0, 1), H^t_{(t+\frac{1}{2})}, (0, 1), (0, 1)).$$

Then $E_1^{(q)}$ defined by $R_2^{(q)}E_1^{(q)}$ being the composition of the restriction to $(0, 1) \times \hat{J}$, followed by an application of

$$G_1 \otimes \text{Id} \otimes \cdots \otimes \text{Id},$$

followed by an extension by 0 to $\hat{\Omega}^{(q-1)}_{k_2} \setminus (-1, 0) \times \hat{J}$, satisfies the assumptions made in Proposition 4.2.
Remark 4.5. The condition that an extension by \( G_1 \) vanishes up to order \( |t + \frac{1}{2}| \) at \(-1\) is fully harmless since it can easily be enforced by multiplying an extension by some smooth cut-off function. The scale-dependent extension that we will discuss in Subsection 5.1 satisfies this boundary condition automatically.

Our main interest of Corollary 4.3 lies in the following:

**Corollary 4.6.** For \( 0 \leq k \leq N \), let \( \Psi_k \) be a Riesz basis for \( L_2(\square_k) \), that renormalized in \( H^s(\square_k) \), is a Riesz basis for \( \tilde{H}^s(\square_k) = H^s_{\tau(k)}(\square) \). Then for \( s \in [0, 1] \), and with \( E \) from Corollary 4.3, the collection \( E(\prod_{k=0}^{N} \Psi_k) \), normalized in the corresponding norm, is a Riesz basis for \([L_2(\Omega), \tilde{H}^s(\Omega)]_{s,2}\).

**Remark 4.7.** Although we allow for \( t \in (0, \frac{1}{2}) \), for these values of \( t \) our exposition is not very relevant. Indeed, for those \( t \), a piecewise tensor product basis can simply be constructed as the union of the tensor product bases on the hypercubes.

To find the corresponding dual basis, we follow Section 2. Taking for \( q = 1, \ldots, N \),

\[
H^{(q)} = L_2(\tilde{\Omega}^{(q)}_k), \quad H_1^{(q)}(\tilde{\Omega}^{(q)}_k),
\]

and with \( \eta_1^{(q)} \) being the extension of functions on \( \tilde{\Omega}^{(q-1)}_{k_1} \) to \( \tilde{\Omega}^{(q)}_k \) by zero, Proposition 2.2 shows that

\[
(E^{(q)})^{-*} = \eta_1^{(q)} (\text{Id} - \eta_1^{(q)} (E_{1}^{(q)})^*) \eta_2^{(q)}.
\]

**Corollary 4.8.** In the situation of Corollary 4.6, let \( \Psi_k \) the Riesz basis for \( L_2(\square_k) \) that is dual to \( \Psi_k \). Then \( E^{-*}(\prod_{k=0}^{N} \tilde{\Psi}_k) \) is the Riesz basis for \( L_2(\tilde{\Omega}) \) that is dual to \( E(\prod_{k=0}^{N} \Psi_k) \). The operator \( E^{-*} \) is the composition for \( q = 1, \ldots, N \) of the mappings \( (E^{(q)})^{-*} \) trivially extended with identity operators in coordinates \( k \in \{ q - 1, \ldots, N \} \setminus \{ k_1^{(q)}, k_2^{(q)} \} \).

Below we give conditions such that \( E^{-*}(\prod_{k=0}^{N} \tilde{\Psi}_k) \), properly scaled, is a Riesz basis for a range of Sobolev spaces with positive smoothness indices, and so, equivalently, \( E(\prod_{k=0}^{N} \Psi_k) \) to be a Riesz basis for the corresponding dual spaces.

For some \( t \in [0, \infty) \setminus \{ N_0 + \frac{1}{2} \} \), to each of the closed facets of all the hypercubes \( \square_k \), we associate a number in \( \{ 0, \ldots, \lfloor t + \frac{1}{2} \rfloor \} \) indicating the order of the Dirichlet boundary condition on that facet. On facets on the boundary of \( \tilde{\Omega} \), this number can be chosen arbitrarily, where on the interior facets it is 0 or \( \lfloor t + \frac{1}{2} \rfloor \).

We define \( \tilde{H}^i(\tilde{\Omega}^{(q)}_{k_1}) \), and so for \( k = q = N \) in particular \( \tilde{H}^i(\Omega) = \tilde{H}^i(\Omega_N^{(N)}) \), to be the closure in \( H^i(\tilde{\Omega}^{(q)}_k) \) of the smooth functions on \( \tilde{\Omega}^{(q)}_k \) that on any of its facets satisfy the boundary conditions that were imposed on each of its subfacets. Note that with some abuse of notation, even when \( t = t \) generally \( \tilde{H}^i(\tilde{\Omega}^{(q)}_{k_1}) \neq \tilde{H}^i(\tilde{\Omega}^{(q)}_{k_2}) \), and that for \( 0 \leq k \leq N \),

\[
\tilde{H}^i(\tilde{\Omega}^{(q)}_k) = \tilde{H}^i(\square_k) = H^i_{\tilde{\sigma}(k)}(\square_k),
\]

for some \( \tilde{\sigma}(k) \in \{ 0, \ldots, \lfloor t + \frac{1}{2} \rfloor \} \).

We make the following assumptions on the selection of the boundary conditions that determine the dual spaces \( \tilde{H}^i(\tilde{\Omega}^{(q)}_k) \):

\( (D_4) \) on the \( \tilde{\Omega}^{(q-1)}_{k_1} \) and \( \tilde{\Omega}^{(q-1)}_{k_2} \) sides of \( J \), the boundary conditions are of order \( \lfloor t + \frac{1}{2} \rfloor \) and 0, respectively,
and, w.l.o.g. assuming that $J = \{0\} \times \hat{J}$ and $(0, 1) \times \hat{J} \subset \Omega_{k_1}^{(q-1)}$,

$$(\mathcal{D}_5')$$ for any function in $\mathcal{E}^i(\hat{\Omega}_{k_2}^{(q-1)})$ that vanishes near $\{-1, 0\} \times \hat{J}$, its reflection in $\{0\} \times \mathbb{R}^{n-1}$ (extended with zero, and then restricted to $\hat{\Omega}_{k_1}^{(q-1)}$) is in $\mathcal{E}^i(\Omega_{k_1}^{(q-1)})$.

**Proposition 4.9.** For $1 \leq q \leq N$, let the extension $E^{(q)}_1$ be of tensor product form as in Proposition 4.4 with $G^*_1 \in B(\mathcal{H}^i_1(\Omega_{k_2}^{(q-1)}), \mathcal{H}^i_1(\Omega_{k_1}^{(q)}))$, and let $\tilde{\Psi}_k$, properly scaled, be a Riesz basis for $\mathcal{H}^i_1(\square_k)$. Then for $s \in [0, 1]$, $E^{-s}(\prod_{k=0}^N \tilde{\Psi}_k)$ is, properly scaled, a Riesz basis for $[L_2(\Omega), \mathcal{H}^i_1(\Omega)]_{s, 2}$.

**Remark 4.10.** The boundary conditions imposed on $G^*_1 u$ at 1 are fully harmless. The scale-dependent extension $G_1$ that we will discuss in Subsection 5.1 satisfies these boundary conditions automatically. On the other hand, thinking of $t \geq t$, the boundary conditions at 0 are, when $t > \frac{1}{2}$, the only properties that are not already implied by the conditions on $G_1$ from Proposition 4.4.

**Proof.** The conditions $(\mathcal{D}_4')$, $(\mathcal{D}_5')$ imply both that $R^{(q)}_2$ has a right-inverse which is in $B(\mathcal{H}^i_1(\Omega_{k_2}^{(q-1)}), \mathcal{H}^i_1(\Omega_{k_1}^{(q)}))$ and $(E^{(q)}_1)^* \in B(\mathcal{H}^i_1(\Omega_{k_1}^{(q)}), \mathcal{H}^i_1(\Omega_{k_1}^{(q-1)}))$, by the assumption on $G^*_1$. Since $R^{(q)}_2 \in B(\mathcal{H}^i_1(\Omega_{k_1}^{(q)}), \mathcal{H}^i_1(\Omega_{k_2}^{(q-1)}))$, $\eta^{(q)}_1(\hat{\Omega}_{k_2}^{(q-1)}) \in B(\mathcal{H}^i_1(\Omega_{k_1}^{(q-1)}), \mathcal{H}^i_1(\Omega_{k_1}^{(q)}))$ directly follow from $(\mathcal{D}_4')$, an $N$-fold application of Proposition 2.4 together with the assumption on the bases $\tilde{\Psi}_k$ completes the proof. 

To end the discussion about the stability of $E(\Pi_{k=0}^N \tilde{\Psi}_k)$ in dual norms, we note that for $t < \frac{1}{2}$, which suffices for our application for solving PDEs, the conditions $(\mathcal{D}_4')$, $(\mathcal{D}_5')$, and those from Proposition 4.9 are void, with the exception of the very mild condition of $\tilde{\Psi}_k$, properly scaled, being a Riesz basis for $\mathcal{H}^i_1(\square_k)$.

The construction of Riesz bases on the reference domain $\hat{\Omega}$ extends to more general domains in a standard fashion. Let $\Omega$ be the image of $\hat{\Omega}$ under a homeomorphism $\kappa$. We define the pull-back $\kappa^*$ by $\kappa^* w = w \circ \kappa$, and so its inverse $\kappa^{-*}$, known as the push-forward, satisfies $\kappa^{-*} v = v \circ \kappa^{-1}$.

**Proposition 4.11.** Let $\kappa^*$ be boundedly invertible as a mapping both from $L_2(\Omega)$ to $L_2(\hat{\Omega})$ and from $H^i(\Omega)$ to $H^i(\hat{\Omega})$. Setting $\mathcal{H}^i(\Omega) := 3 \kappa^{-*}|_{\mathcal{H}^i(\hat{\Omega})}$, we have that $\kappa^{-*} \in B([L_2(\Omega), \mathcal{H}^i(\Omega)]_{s, 2}, [L_2(\hat{\Omega}), \mathcal{H}^i(\hat{\Omega})]_{s, 2})$ is boundedly invertible ($s \in [0, 1]$). So if $\Psi$ is a Riesz basis for $L_2(\Omega)$ and, properly scaled, for $\mathcal{H}^i(\Omega)$, then for $s \in [0, 1]$, $\kappa^{-*} \Psi$ is, properly scaled, a Riesz basis for $[L_2(\hat{\Omega}), \mathcal{H}^i(\hat{\Omega})]_{s, 2}$.

If $\hat{\Psi}$ is the collection dual to $\Psi$, then $|\det D\kappa^{-1}(\cdot)|\kappa^{-*} \hat{\Psi}$ is the collection dual to $\kappa^{-*} \Psi$.

5. Approximation by piecewise tensor product wavelets

In the setting of Proposition 4.4, Corollary 4.6 and Proposition 4.9, writing $\square_k = \square + \alpha_k$, where $\alpha_k \in \mathbb{Z}^n$, we select the primal and dual bases for $L_2(\square_k)$ to be

$$\Psi^{(k)}(\sigma, \sigma) \left( \cdot - \alpha_k \right), \quad \hat{\Psi}^{(k)}(\sigma, \sigma) \left( \cdot - \alpha_k \right)$$

as constructed in Section 3, which, properly scaled, are Riesz bases for $H^i_{\sigma(k)}(\square_k)$ and $H^i_{\hat{\sigma}(k)}(\square_k)$, respectively.
In the setting of Proposition 4.11, for \( m \in \{0, \ldots, |t|\} \) and \( u \in \hat{H}^m(\Omega) := [L_2(\Omega), H^t(\Omega)]_{m/t, 2} \), with additionally

\[
\kappa^* \left( \sum_{k=0}^{N} \mathcal{H}^d_{m, \theta}(\Box_k) \right) := \{ v : \Omega \to \mathbb{R} : v \circ \kappa \in \mathcal{H}^d_{m, \theta}(\Box_k) \},
\]

we study approximation rates from \( \kappa^* \mathcal{E} \left( \sum_{k=0}^{N} \Psi_{\sigma(k), \sigma(\kappa)}(-\alpha_k) \right) \) in the \( H^m(\Omega) \)-norm. Since, as is assumed in Proposition 4.11, \( \kappa^* \in B(\hat{H}^m(\Omega), \hat{H}^m(\Omega)) \) is boundedly invertible, it is sufficient to study this issue for the case that \( \kappa = \text{Id} \) and so \( \Omega = \hat{\Omega} \).

We will apply extension operators \( E^{(q)}_1 \) that are built from univariate extension operators. The latter will be chosen such that the resulting primal and dual wavelets on \( \hat{\Omega} \) are, restricted to each \( \Box_k \subset \Omega \), tensor products of collections of univariate functions that are local and locally finite (cf. parts (1) and (2) of the forthcoming Proposition 5.4).

### 5.1. Construction of scale-dependent extension operators.

We make the following additional assumptions on the univariate wavelets. For \( \tilde{\sigma} = (\sigma_t, \sigma_r) \in \{0, \ldots, [t + \frac{1}{2}]\}, \tilde{\sigma} = (\sigma_t, \sigma_r) \in \{0, \ldots, [t + \frac{1}{2}]\}, \) and with \( \tilde{\theta} := (0, 0), \)

\[
(W_7) \quad V_j^{(\tilde{\sigma})} := \text{span} \{ \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})} : \lambda \in \nabla_{\tilde{\sigma}, \tilde{\theta}}, |\lambda| \leq j \} \text{ is independent of } \tilde{\sigma}, \quad V_j^{(\tilde{\sigma})} = V_j^{(\tilde{\theta})} \cap H^t(I),
\]

\[
(W_8) \quad \nabla_{\tilde{\sigma}, \tilde{\theta}} \text{ is the disjoint union of } \nabla_{\sigma_t, \sigma_r}, \nabla^{(r)}_{\sigma_r}, \nabla^{(r)}_{\sigma_r, \sigma_r}, \text{ such that}
\]

\[
(i) \quad \sup_{\lambda \in \nabla_{\tilde{\sigma}, \tilde{\theta}}, x \in \text{supp } \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})}} 2^{|\lambda||x|} \leq \rho, \quad \sup_{\lambda \in \nabla^{(r)}_{\sigma_r}, x \in \text{supp } \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})}} 2^{|\lambda||1-x|} \leq \rho,
\]

\[
(ii) \quad \text{for } \lambda \in \nabla^{(r)}_{\sigma_r}, \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})} = \psi_{\lambda}^{(\tilde{\theta})}, \tilde{\psi}_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})} = \tilde{\psi}_{\lambda}^{(\tilde{\theta})}, \text{ and the extensions of } \psi_{\lambda}^{(\tilde{\theta})} \text{ and } \tilde{\psi}_{\lambda}^{(\tilde{\theta})} \text{ by zero are in } H^t(\mathbb{R}) \text{ and } H^t(\mathbb{R}), \text{ respectively.}
\]

\[
(W_9) \quad \text{span} \{ \psi_{\lambda}^{(\tilde{\theta})} \mid 1 - \lambda \in \nabla^{(r)}_{\sigma_r}, |\lambda| = j \} \text{ is span} \{ \psi_{\lambda}^{(\tilde{\theta})} : \lambda \in \nabla^{(r)}_{\sigma_r}, |\lambda| = j \},
\]

\[
(W_{10}) \quad \text{span} \{ \psi_{\lambda}^{(\tilde{\sigma}, \tilde{\theta})} : \mu \in \nabla^{(r)}_{\sigma_r, \sigma_r} \} \quad (l \in \mathbb{N}_0, \mu \in \nabla^{(r)}_{\sigma_r, \sigma_r}),
\]

As \( (W_1)-(W_6) \), these conditions are satisfied by following the biorthogonal wavelet constructions on the interval from [Pri10, Dij09] \( (W_7) \) is not satisfied by the construction from [DKU99], but the following exposition can be adapted to apply to these wavelets as well.

**Remark 5.1.** In view of the boundary conditions that are imposed on the interfacers, see \( (D_4) \) and \( (D'_4) \), it is actually sufficient to impose \( (W_7)-(W_{10}) \) for \( (\sigma_t, \tilde{\sigma}_t), (\sigma_r, \tilde{\sigma}_r) \in \{( [t + \frac{1}{2}], 0), (0, [t + \frac{1}{2}]) \} \).

We consider the setting of Proposition 4.4. W.l.o.g. we assume that \( J = \{0\} \times \hat{J}, \) and \( (0, 1) \times \hat{J} \subset \mathcal{G}^{(q-1)}_{k_1} \). We assume to have available a univariate extension operator

\[
\mathcal{G}_1 \in B(L_2(0, 1), L_2(-1, 1)) \text{ with } \mathcal{G}_1 \in B(L_2(-1, 1), H^t_{((t+\frac{1}{2}), 0)}(0, 1)).
\]
Let $\eta_1$ and $\eta_2$ denote the extensions by zero of functions on $(0, 1)$ or on $(-1, 0)$ to functions on $(-1, 1)$, with $R_1$ and $R_2$ denoting their adjoints. We assume that $\tilde{G}_1$ and its “adjoint extension”

$$\tilde{G}_2 := (\text{Id} - \eta_1 \tilde{G}_1^*) \eta_2$$

(cf. Remark 2.3) are local in the sense that

$$\begin{align}
\text{diam}(\text{supp } R_2 \tilde{G}_1 u) &\lesssim \text{diam}(\text{supp } u) \quad (u \in L_2(0, 1)), \\
\text{diam}(\text{supp } R_1 \tilde{G}_2 u) &\lesssim \text{diam}(\text{supp } u) \quad (u \in L_2(-1, 0)),
\end{align}$$

(5.3) see Figure 4 for an illustration.

![Figure 4. Univariate extensions and restrictions.](image)

Examples are given by Hestenes extensions ([Hes41, DS99, KS06]), which are of the form

$$\tilde{G}_1 v(-x) = \sum_{l=0}^{L} \gamma_l(\zeta(x) (\beta_l x) \quad (v \in L_2(\mathcal{I}), x \in \mathcal{I}),$$

(5.4) and, being an extension, $\tilde{G}_1 v(x) = v(x)$ for $x \in \mathcal{I}$, where $\gamma_l \in \mathbb{R}$, $\beta_l > 0$, and $\zeta : [0, \infty) \to [0, \infty)$ is some smooth cut-off function with $\zeta \equiv 1$ in a neighborhood of 0, and $\text{supp } \zeta \subset [0, \min_l (\beta_l, \beta_l^{-1})]$. Its adjoint reads as

$$\tilde{G}_1^* w(x) = w(x) + \zeta(x) \sum_{l=0}^{L} \frac{\gamma_l}{\beta_l} w\left(\frac{-x}{\beta_l}\right) \quad (w \in L_2(-1, 1), x \in \mathcal{I}).$$

A Hestenes extension satisfies (5.2) if and only if

$$\sum_{l=0}^{L} \gamma_l \beta_l^j = (-1)^i (N_0 \ni i \leq \lceil t - \frac{1}{2} \rceil), \quad \sum_{l=0}^{L} \gamma_l \beta_l^{-j+1} = (-1)^{i+1} (N_0 \ni j \leq \lceil t - \frac{1}{2} \rceil).$$

With a univariate extension $\tilde{G}_1$ as in (5.2) at hand, the obvious approach is to define $E_1^{(q)}$ according to Proposition 4.4 with $G_1 = \tilde{G}_1$. A problem with the choice $G_1 = \tilde{G}_1$ is that generally (5.3) does not imply the desirable property that $\text{diam}(\text{supp } G_1 u) \lesssim \text{diam}(\text{supp } u)$. Indeed, think of the application of a Hestenes extension to a $u$ with a small support that is not located near the interface.

To solve this and the corresponding problem for the adjoint extension, in any case for $u$ being any primal or dual wavelet, respectively, following [DS99] we will apply our construction using the modified, scale-dependent univariate extension operator

$$G_1 : u \mapsto \sum_{\lambda \in \psi_{0,0}^{(r)}} \langle u, \psi_{\lambda}^{(\bar{0}, \bar{0})} \rangle_{L_2(\mathcal{I})} \tilde{G}_1 \psi_{\lambda}^{(\bar{0}, \bar{0})} + \sum_{\lambda \in \psi_{0,0}^{(r)}} \langle u, \psi_{\lambda}^{(\bar{0}, \bar{0})} \rangle_{L_2(\mathcal{I})} \eta_1 \psi_{\lambda}^{(\bar{0}, \bar{0})}.$$
Taking $\tilde{G}_1$ to be a Hestenes extension, under the condition of $\rho$ being sufficiently small, its first advantage is that its application in (5.5) does not “see” the cut-off function $\zeta$, which prevents potential quadrature problems.

**Proposition 5.2.** Assuming $\rho$ to be sufficiently small, the scale-dependent extension $G_1$ from (5.5) satisfies, for $\sigma \in \{0, \ldots, \lfloor t + \frac{1}{4} \rfloor \}^2$, $\tilde{\sigma} \in \{0, \ldots, \lfloor \tilde{t} + \frac{1}{4} \rfloor \}^2$

\[
G_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})} = \begin{cases} 
\eta_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})} & \text{when } \mu \in \nabla^{(I)} \cup \nabla^{(r)}_{\sigma^r, \zeta}, \\
\tilde{G}_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})} & \text{when } \mu \in \nabla^{(l)}_{\sigma^l, \zeta}.
\end{cases}
\]

Assuming, additionally, $\tilde{G}_1$ to be a Hestenes extension with $\beta_l = 2^{l_1}$, the resulting adjoint extension $G_2 := (\text{Id} - \eta_1G_1^*)\eta_2$ satisfies

\[
G_2(\tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}(1 + \cdot)) = \begin{cases} 
\eta_2\tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}(1 + \cdot) & \text{when } \mu \in \nabla^{(I)} \cup \nabla^{(l)}_{\sigma^l, \zeta}, \\
\tilde{G}_2\tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}(1 + \cdot) & \text{when } \mu \in \nabla^{(r)}_{\sigma^r, \zeta},
\end{cases}
\]

We have $G_1 \in B(L_2(0,1), L_2(-1,1))$, $G_1 \in B(H^\ell(0,1), H^\ell(-1,1))$, and $G_1^* \in B(H^\ell(-1,1), H^{\ell+\frac{1}{2}}(0,1))$.

Finally, for $\mu \in \nabla^{(r)}_{\sigma^r, \zeta}$, it holds that

\[
\text{diam}(\text{supp} \tilde{G}_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}) \lesssim \text{diam}(\text{supp} \psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}),
\]

\[
\text{diam}(\text{supp} \tilde{G}_2\tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}) \lesssim \text{diam}(\text{supp} \tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}).
\]

**Proof.** By $(W_9)(ii)$, for $\mu \in \nabla^{(I)} \cup \nabla^{(r)}_{\sigma^r, \zeta}$, $\lambda \in \nabla^{(l)}_{0,0}$, one has $\langle \psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}, \tilde{\psi}_\lambda^{(0,0)} \rangle_{L_2(I)} = 0$, and so $G_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})} = \sum_{\lambda \in \nabla^{(l)}_{0,0}} \langle \psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}, \tilde{\psi}_\lambda^{(0,0)} \rangle_{L_2(I)}\eta_1\psi_\lambda^{(0,0)} = \eta_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}$, the last equality from $\tilde{\psi}_\lambda^{(0,0)}$ being a Riesz basis for $L_2(I)$, and $\eta_1$ being $L_2$-bounded.

Similarly, for $\mu \in \nabla^{(r)}_{\sigma^r, \zeta}$, $\lambda \in \nabla^{(I)} \cup \nabla^{(r)}_{0,0}$, it holds that $\langle \psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}, \tilde{\psi}_\lambda^{(0,0)} \rangle_{L_2(I)} = 0$, and so $G_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})} = \sum_{\lambda \in \nabla^{(l)}_{0,0}} \langle \psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}, \tilde{\psi}_\lambda^{(0,0)} \rangle_{L_2(I)}\tilde{G}_1\psi_\lambda^{(0,0)} = \tilde{G}_1\psi_\mu^{(\tilde{\sigma}, \tilde{\sigma})}$.

If $G_1$ is a Hestenes extension with $\beta_l = 2^{l_1}$, then for $v \in L_2(I)$,

\[
G_1^*\eta_2(\psi v(1 + \cdot)) = \sum_{\lambda \in \nabla^{(l)}_{0,0}} \langle G_1^*\eta_2 v(1 + \cdot), \tilde{\psi}_\lambda^{(0,0)} \rangle_{L_2(I)} \tilde{\psi}_\lambda^{(0,0)}
\]

\[
= \sum_{\lambda \in \nabla^{(l)}_{0,0}} \langle v(1 - \cdot), (R_2 G_1^*\psi_\lambda^{(0,0)})(1 - \cdot) \rangle_{L_2(I)} \tilde{\psi}_\lambda^{(0,0)}
\]

\[
= \sum_{\lambda \in \nabla^{(r)}_{0,0}} \langle v(1 - \cdot), (R_2 \tilde{G}_1\psi_\lambda^{(0,0)})(1 - \cdot) \rangle_{L_2(I)} \tilde{\psi}_\lambda^{(0,0)}
\]

\[
= \sum_{\lambda \in \nabla^{(r)}_{0,0}} \langle v(1 - \cdot), \sum_{l=0}^L \gamma_l \psi_\lambda^{(0,0)}(2^{l_1}) \rangle_{L_2(I)} \tilde{\psi}_\lambda^{(0,0)}.
\]

For $v = \tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}$ and $\mu \in \nabla^{(I)} \cup \nabla^{(r)}_{\sigma^r, \zeta^r}$, (5.9) is zero by $(W_9)$, $(W_{10})$, and $(W_8)(ii)$. For $v = \tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}$ and $\mu \in \nabla^{(r)}_{\sigma^r, \zeta^r}$, one has $\langle v(1 - \cdot), \sum_{l=0}^L \gamma_l \psi_\lambda^{(0,0)}(2^{l_1}) \rangle_{L_2(I)} = 0$ for $\lambda \in \nabla^{(I)} \cup \nabla^{(r)}_{0,0}$ by $(W_9)$, $(W_{10})$, and $(W_8)(ii)$. So for those $\mu$, one has $G_1^*\eta_2 \tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})} = \tilde{G}_1^*\eta_2 \tilde{\psi}_\mu^{(\tilde{\sigma}, \tilde{\sigma})}$, which completes the proof of (5.7).
Although implicitly claimed otherwise in [DS99, (4.3.12)], we note that boundedness of $G$ by the application of $\tilde{\Psi}$ splitting of both $L$ approximation rates provided by the primal piecewise tensor product wavelets.

The mapping $P : u \mapsto \sum_{\mu \in \nabla^{(i)} \cup \nabla^{(r)}_{0,0}} \langle u, \psi_{\mu(\bar{\sigma}, \bar{\delta})}((1 + \cdot)) \rangle_{L_2(-1,0)}(\tilde{\Psi}_{\mu(\bar{\sigma}, \bar{\delta})}(1 + \cdot))$ is in $B(H^l(-1,1), H^l(-1,1))$ by the assumption on $\tilde{\Psi}(\bar{\sigma}, \bar{\delta})$ and $(W_k)_{(ii)}$. Since $\tilde{\Psi}(\bar{\sigma}, \bar{\delta})(1 + \cdot)$ is a Riesz basis for $L_2(-1,0)$,

$$R_2(I - P)u = \sum_{\mu \in \nabla^{(r)_{\bar{\sigma}, \bar{\delta}}} \sigma} \langle u, \psi_{\mu(\bar{\sigma}, \bar{\delta})}(1 + \cdot) \rangle_{L_2(-1,0)}(\tilde{\Psi}_{\mu(\bar{\sigma}, \bar{\delta})}(1 + \cdot)).$$

We conclude that $(G_1^* - \tilde{G}_1^*)\eta_2 R_2(I - P) = 0$. Since $G_1$ and $\tilde{G}_1$ are extensions, we also have $G_1^* \eta_1 = \text{Id} = \tilde{G} - 1^* \eta_1$, and so $G_1^*(I - P) = G_1^*(\eta_1 R_1 + \eta_2 R_2)(I - P) = \tilde{G}_1^*(I - P)$. Together with $G_1 P = 0$, from (5.2) we conclude that $G_1^* \in B(H^l(-1,1), H^l((-1 + \frac{1}{2}), 0, 1))$.

The last statement is a direct consequence of (5.6) and (5.7).

Remark 5.3. Although implicitly claimed otherwise in [DS99, (4.3.12)], we note that (5.7), and so (5.8), cannot be expected for $\tilde{G}_1$ being a general Hestenes extension as given by (5.4), so without assuming that $\beta_l = 2^l$.

Moreover, (5.7), and so (5.8), are only guaranteed when, for $(\sigma_l, \delta_l) = (0, \lfloor \frac{l + \frac{3}{2} - 1}{2} \rfloor)$, for any $\lambda \in \nabla_{\bar{\sigma}, \bar{\delta}}$ for which either $\psi_{\lambda(\bar{\sigma}, \bar{\delta})}$ or $\tilde{\psi}_{\lambda(\bar{\sigma}, \bar{\delta})}$ “depends on” the boundary conditions imposed at the left boundary, the primal wavelet $\psi_{\lambda(\bar{\sigma}, \bar{\delta})}$ is extended by the application of $\tilde{G}_1$. The reason to emphasize this is that with common biorthogonal wavelet constructions on the interval, the number of dual wavelets that depend on the boundary conditions is larger than that of the primal ones. Note that even if dual wavelets may not enter the computations, their locality as given by (5.8) will be used to prove the forthcoming Theorem 5.6 about the approximation rates provided by the primal piecewise tensor product wavelets.

Some examples of relevant Hestenes extensions with $\beta_l = 2^l$ are:

- $L = 0$, $\gamma_0 = 1$ (reflection). Satisfies (5.2) for $t < \frac{3}{2}$, $\tilde{t} < \frac{1}{2}$.
- $L = 1$, $\gamma_0 = 3$, $\gamma_1 = -2$. Satisfies (5.2) for $t < \frac{5}{2}$, $\tilde{t} < \frac{3}{2}$.
- $L = 1$, $\gamma_0 = -3$, $\gamma_1 = 4$. Satisfies (5.2) for $t < \frac{5}{2}$, $\tilde{t} < \frac{3}{2}$.
- $L = 2$, $\gamma_0 = -5$, $\gamma_1 = 10$, $\gamma_2 = -4$. Satisfies (5.2) for $t < \frac{5}{2}$, $\tilde{t} < \frac{3}{2}$.

In order to identify individual wavelets from the collections constructed by the applications of the extension operators, we have to introduce some more notations. For $0 \leq q \leq N$, we set the index sets

$$\nabla^{(0)}_k := \nabla_{\sigma(k), \bar{\delta}(k)} \times \{k\}$$

and, for $q > 0$,

$$\nabla^{(q)}_k := \begin{cases} \nabla^{(q-1)}_{k_1} \cup \nabla^{(q-1)}_{k_2} & \text{if } k = \hat{k}, \\ \nabla^{(q-1)}_{k_1} & \text{if } k \in \{q, \ldots, N\} \setminus \{\hat{k}\} \text{ and } \Omega^{(q)}_k = \Omega^{(q-1)}_k, \end{cases}$$

and, for $(\lambda, p) \in \nabla^{(q)}_k$, the primal and dual wavelets,

$$\psi^{(0,k)}_{\lambda,p} := \psi^{(p, \bar{\sigma}(p), \bar{\delta}(p))}(\cdot - \alpha_p), \quad \tilde{\psi}^{(0,k)}_{\lambda,p} := \tilde{\psi}^{(p, \bar{\sigma}(p), \bar{\delta}(p))}(\cdot - \alpha_p).$$
and, for \( q > 0 \),

\[
\Psi_{\lambda,p}^{(q,k)} := \begin{cases} 
E_1^{(q)} \psi_{\lambda,p}^{(q-1,k_1)} (\lambda, p) \in \nabla_{k_1}^{(q-1)} & \text{if } k = \bar{k}, \\
\eta_2^{(q)} \psi_{\lambda,p}^{(q-1,k_2)} (\lambda, p) \in \nabla_{k_2}^{(q-1)} & \text{if } k \in \{q, \ldots, N\} \setminus \{\bar{k}\} \text{ and } \Omega_k^{(q)} = \Omega_{k-1}^{(q-1)}, 
\end{cases}
\]

\[
\gamma_{\lambda,p}^{(q,k)} := \begin{cases} 
\eta_1^{(q)} \tilde{\psi}_{\lambda,p}^{(q-1,k_1)} (\lambda, p) \in \nabla_{k_1}^{(q-1)} & \text{if } k = \bar{k}, \\
(\text{Id} - \eta_1^{(q)} (E_1^{(q)})^*) \eta_2^{(q)} \tilde{\psi}_{\lambda,p}^{(q-1,k_2)} (\lambda, p) \in \nabla_{k_2}^{(q-1)} & \text{if } k \in \{q, \ldots, N\} \setminus \{\bar{k}\} \text{ and } \Omega_k^{(q)} = \Omega_{k-1}^{(q-1)}, 
\end{cases}
\]

Then, as we have seen,

\[
(\Psi_{k}^{(q)}, \tilde{\Psi}_{k}^{(q)} : (\lambda, p) \in \nabla_{k}^{(q)}), \{\gamma_{\lambda,p}^{(q,k)} (\lambda, p) \in \nabla_{k}^{(q)}\}
\]

is a pair of biorthogonal Riesz bases for \( L_2 (\tilde{\Omega}_k^{(q)}) \), and for \( s \in [0, 1] \), \( \Psi_{k}^{(q)} \) or \( \tilde{\Psi}_{k}^{(q)} \) are, properly scaled, Riesz bases for \( L_2 (\tilde{\Omega}_k^{(q)}), \tilde{H}^r (\hat{\Omega}_k^{(q)}) \), and \( L_2 (\tilde{\Omega}_k^{(q)}), \tilde{H}^r (\hat{\Omega}_k^{(q)}) \), respectively.

**Proposition 5.4.** With \( E_1^{(q)} \) being defined using the scale-dependent extension operator as in Proposition 5.2, for \( 0 \leq q \leq k \leq N \), we have

1. \( \supp \Psi_{\lambda,p}^{(q,k)} \), \( \supp \gamma_{\lambda,p}^{(q,k)} \) are contained in a hyperrectangle aligned with the Cartesian coordinates with sides in length of order \( 2^{-|\lambda|} \).
2. for any \( y \in \mathbb{R}^n \) and \( j \in \mathbb{N}_0^n \), the hyperrectangle \( y + \prod_{i=1}^n [0, 2^{-j}] \) is intersected by the supports at most a uniformly bounded number of primal or dual wavelets \( \psi_{\lambda,p}^{(q,k)}, \tilde{\psi}_{\lambda,p}^{(q,k)} \) with \( |\lambda| = j \).

3. let

\[
V_j (\hat{\Omega}_k^{(q)}) := \{ u \in \tilde{H}^r (\hat{\Omega}_k^{(q)}) : u (\cdot + \alpha_k) \in \bigotimes_{i=1}^n V_{\alpha_i}^{(q)} (L_k^{(q)} \subset \hat{\Omega}_k^{(q)}) \}
\]

\[
Z_j (\hat{\Omega}_k^{(q)}) := \text{span} \{ \psi_{\lambda,p}^{(q,k)} (\lambda, p) \in \nabla_{k}^{(q)}, |\lambda| \leq j \},
\]

and \( e := (1, \ldots, 1)^T \in \mathbb{R}^n \). Then for some constants \( m_q, M_q \in \mathbb{N}_0 \), for all \( j \in \{m_q, m_q + 1, \ldots \}^n \),

\[
V_{j+m_q e} (\hat{\Omega}_k^{(q)}) \subset Z_j (\hat{\Omega}_k^{(q)}) \subset V_{j+M_q e} (\hat{\Omega}_k^{(q)}).
\]

**Proof.** Parts (1) and (2) follow from the locality and the locally finiteness of the univariate primal and dual wavelets \( (W_5) \) and \( (W_6) \), and the locality of the extension and the adjoint extension given by (5.6) and (5.7). By construction of the wavelet basis, the second inclusion in (3) follows from (5.6) and \( \hat{G}_1 \) being a Hestenes extension with \( \beta_1 = \beta_1^* \), \( (W_{10}) \), \( (W_5) \), and \( (W_7) \). The constant \( M_q \) can be taken to be less than or equal to \( 2L \), or to \( L \) when the domain has no cracks.

The first inclusion in (3) holds true for \( q = 0 \) with \( m_0 = 0 \) by \( (W_7) \). Suppose, for some \( m_k \), it is true for \( q-1 \) and \( q-1 \leq k \leq N \). For some constant \( m_q \geq m_{q-1} \) that will be determined below, let \( v \in V_{j-m_q e} (\hat{\Omega}_k^{(q-1)}) \). Then \( R_1^{(q)} v \in V_{j-m_q e} (\hat{\Omega}_k^{(q-1)}) \subset Z_{j+(m_q-1-m_k)e} (\hat{\Omega}_k^{(q-1)}) \), and so

\[
E_1^{(q)} R_1^{(q)} v \in Z_{j+(m_q-1-m_k)e} (\hat{\Omega}_k^{(q-1)}) \subset Z_j (\hat{\Omega}_k^{(q)})
\]

by definition of \( \Psi_{k}^{(q)} \).
From (5.10), we have $E_1^{(q)} R_1^{(q)} v \in V_{j+1,M_q} \subset V_{j+1+M_q} \subset V_{j+1+M_q} \subset (\hat{\Omega}_k^{(q)})$, and so $(I-E_1^{(q)} R_1^{(q)}) v \in V_{j+1+M_q} \subset (\hat{\Omega}_k^{(q)})$, and therefore

$$R_2^{(q)} (I-E_1^{(q)} R_1^{(q)}) v \in \{ u \in L_2(\hat{\Omega}_k^{(q-1)}) : |u(\cdot + \alpha_k)|_{\square} \in \mathbb{R}_{j+1+m_q+M_q} \} \subset \Omega_k^{(q-1)}$$

Since, as shown in the proof of Proposition 4.2, $(I-E_1^{(q)} R_1^{(q)}) v \in \hat{H}_t^{(\hat{\Omega}_k^{(q-1)})}$, and so $R_2^{(q)} (I-E_1^{(q)} R_1^{(q)}) v \in \hat{H}_t^{(\hat{\Omega}_k^{(q-1)})}$, we infer that $R_2^{(q)} (I-E_1^{(q)} R_1^{(q)}) v \in V_{j+1+M_q} \subset (\hat{\Omega}_k^{(q-1)}) \subset Z_{j+1+M_q} \subset (\hat{\Omega}_k^{(q-1)})$. By taking $m_q = 2m_q-1 + M_q$, we conclude that $(I-E_1^{(q)} R_1^{(q)}) v = E_1^{(q)} R_1^{(q)}) v \in E_1^{(q)} R_1^{(q)}) v \in Z_{j+1+M_q} \subset (\hat{\Omega}_k^{(q-1)})$ by definition of $\Psi_k^{(q)}$. Together with (5.10), this completes the proof.

Remark 5.5. The above proof shows that for $L = 0$ (reflection), $V_{j+1+M_q} \subset (\hat{\Omega}_k^{(q-1)})$.

Now we are ready to study the question, raised at the beginning of this section, about the rate of approximation in $H^m(\hat{\Omega})$.

**Theorem 5.6.** Let the $E_1^{(q)}$ be defined using the scale-dependent extension operators as in Proposition 5.2. Then for any $\theta \in [0, d]$, and any $0 \leq q \leq k \leq N$, there exists a (nested) sequence $(\nabla_{k,M}^{(q)})_{M \in \mathbb{N}} \subset \nabla_k^{(q)}$ with $\# \nabla_{k,M}^{(q)} \approx M$, such that

$$(\nabla_{k,M}^{(q)}) = \inf_{v \in \text{span} \{ \psi_{\lambda,p}^{(q,k)} : (\lambda,p) \in \nabla_{k,M}^{(q)} \}} \| u - v \|_{H^m(\hat{\Omega}_k^{(q)})} \lesssim M^{-(d-m)} \sum_{\square \subset \hat{\Omega}_k^{(q)}} \| u \|_{H^m(\hat{\Omega}_k^{(q)})}^2$$

for any $u \in \hat{H}_t^{m(\hat{\Omega}_k^{(q)})}$ for which the right-hand side is finite (for $q = k = N$, i.e., for $\hat{\Omega}_k^{(q)} = \hat{\Omega}_k$, this is equivalent to saying that $u$ satisfies (5.1) (with $\kappa = \text{Id}$)).

For $m = 0$, the factor $M^{-(d-m)}$ in (5.11) has to be read as $(\log M)^{(n-1)}(\frac{1}{2}+d) M^{-d}$.

**Proof.** We prove the statement with the additional property that the index sets $\nabla_{k,M}^{(q)}$ have the multiple tree property introduced in Theorem 3.2 for subsets of $\nabla_{(\sigma,\tilde{\sigma})}$, and that in the current generalized setting reads as: For any $(\lambda,p) \in \nabla_{k,M}^{(q)}$ and any $\bar{j} \in \mathbb{N}_0^k$ with $\bar{j} \leq |\lambda|$, there exists a $(\lambda',p') \in \nabla_{k,M}^{(q)}$ with $|\lambda'| = \bar{j}$, and $\text{supp} \psi_{\lambda,p}^{(q,k)} \cap \text{supp} \psi_{\lambda',p'}^{(q,k)} = \emptyset$.

For $q = 0$, the so extended statement is equal to that of Theorem 3.2. Let us assume that the statement is valid for some $0 \leq q-1 \leq N-1$.

To prove the statement for $q$, it is sufficient to consider $k = \bar{k}$. Let $\varphi$ be a smooth function on $\mathbb{R}^n$ such that for some sufficiently small $\varphi_1 > \varphi_1 > 0$, $\varphi \equiv 1$ within distance $\varphi_1$ of the interface $J$ between $\hat{\Omega}_k^{(q-1)}$ and $\hat{\Omega}_k^{(q-1)}$, and vanishes outside distance $\varphi_2$ of $J$. Writing any function $v$ on $\hat{\Omega}_k^{(q)}$ by $\varphi v + (1-\varphi) v$ induces a stable splitting of $H^m(\hat{\Omega}_k^{(q)}) \cap \bigcap_{\square \subset \hat{\Omega}_k^{(q)} \| u \|_{H^m(\hat{\Omega}_k^{(q)})}^2}$ into two subspaces.

For functions $u$ of type $(1-\varphi) v$, one has $u|_{\hat{\Omega}_k^{(q-1)}} \in \hat{H}_t^{m(\hat{\Omega}_k^{(q-1)})}$, and, assuming $\rho$ to be sufficiently small, $\langle u|_{\hat{\Omega}_k^{(q-1)}}, \psi_{\lambda,p}^{(q-1,k_1)} \rangle_{L_2(\hat{\Omega}_k^{(q-1)})} = 0$ for all $(\lambda,p) \in \nabla_{k_1}^{(q-1)}$ with $\eta_1^{(q)} \psi_{\lambda,p}^{(q-1,k_1)} \neq E_1^{(q)} \psi_{\lambda,p}^{(q-1,k_1)}$. We conclude that for such functions (5.11) is
valid when
\[ \nabla^{(q)}_{k,M} \supseteq \nabla^{(q-1)}_{k_1,M} \cup \nabla^{(q-1)}_{k_2,M}. \]

In the remainder of this proof, we consider functions of type \( u = \varrho v \), so with support inside some sufficiently small neighborhood of \( J \). For \( q - 1 \leq k \leq N \), we set the biorthogonal projectors
\[ P^{(q-1)}_{k,M} : v \mapsto \sum_{(\lambda,p) \in \nabla^{(q-1)}_{k,M}} \langle v, \tilde{\psi}_{\lambda,p}^{(q-1,k)} \rangle_{L^2(\hat{\Omega}^{(q-1)}_k)} \phi^{(q-1,k)}_{\lambda,p} \]
W.l.o.g. we assume \( J = \{ 0 \} \times \bar{J} \) and define the (scale-independent) extension \( \hat{E}^{(q)}_1 \) as \( E^{(q)}_1 \) with \( G_1 \) reading as \( \hat{G}_1 \), defined by \( \hat{G}_1 v(\cdot - x) = \sum_{l=0}^L \gamma_l v(2^l x) \) and \( \hat{G}_1 v(x) = v(x) \) (\( x \in \bar{J} \)). So \( G_1 \) is the Hestenes extension \( \hat{G}_1 \) without the smooth cut-off function which is not needed here because of the assumption on \( \text{supp} \ u \).

It holds that \( R^{(q)}_2 (\text{Id} - \hat{E}^{(q)}_1 R^{(q)}_1) u \in \hat{H}^m(\hat{\Omega}^{(q-1)}_{k_2}) \) and \( R^{(q)}_1 u \in \hat{H}^m(\hat{\Omega}^{(q-1)}_{k_1}) \). Since \( \hat{E}^{(q)}_1 \) preserves the piecewise weighted Sobolev smoothness of a function supported near the interface, we have
\[
\sum_{\Box \subset \hat{\Omega}^{(q-1)}_{k_2}} \| R^{(q)}_2 (\text{Id} - \hat{E}^{(q)}_1 R^{(q)}_1) u \|_{H^m_{\rho}(\Box)}^2 + \sum_{\Box \subset \hat{\Omega}^{(q-1)}_{k_1}} \| R^{(q)}_1 u \|_{H^m_{\rho}(\Box)}^2
\]
\[
\lesssim \sum_{\Box \subset \hat{\Omega}^{(q-1)}_{k_2}} \| u \|_{H^{d}_{\rho}(\Box)}^2.
\]

Setting \( u_1 := P^{(q-1)}_{k_1,M} R^{(q)}_1 u \), \( u_2 := P^{(q-1)}_{k_2,M} R^{(q)}_2 (\text{Id} - \hat{E}^{(q)}_1 R^{(q)}_1) u \), from \( [\hat{E}^{(q)}_1 \eta^{(q)}_2] \in B(\hat{H}^m(\hat{\Omega}^{(q-1)}_{k_1})) \times \hat{H}^m(\hat{\Omega}^{(q-1)}_{k_2}), \hat{H}^m(\hat{\Omega}^{(q)}_{k})) \) (see Proposition 4.2), we conclude that
\[
\| u - (\hat{E}^{(q)}_1 u_1 + \eta^{(q)}_2 u_2) \|_{H^m(\hat{\Omega}^{(q)}_k)} = \left\| [\hat{E}^{(q)}_1 \eta^{(q)}_2] \left( \begin{bmatrix} R^{(q)}_1 \\ R^{(q)}_2 (\text{Id} - \hat{E}^{(q)}_1 R^{(q)}_1) \end{bmatrix} u - \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \right) \right\|_{H^m(\hat{\Omega}^{(q)}_k)}
\]
\[
\lesssim \sqrt{\| R^{(q)}_1 u - u_1 \|^2_{H^m(\hat{\Omega}^{(q-1)}_{k_1})} + \| R^{(q)}_2 (\text{Id} - \hat{E}^{(q)}_1 R^{(q)}_1) u - u_2 \|^2_{H^m(\hat{\Omega}^{(q-1)}_{k_2})}}
\]
\[
\lesssim M^{-(d-m)} \sqrt{\sum_{\Box \subset \hat{\Omega}^{(q)}_k} \| u \|_{H^m_{\rho}(\Box)}^2},
\]
the last inequality by the induction hypothesis and (5.12).

Next, we write
\[
\| u - (\hat{E}^{(q)}_1 u_1 + \eta^{(q)}_2 u_2) \|_{H^m(\hat{\Omega}^{(q)}_k)} = u - (\hat{E}^{(q)}_1 u_1 + \eta^{(q)}_2 u_2) + (\hat{E}^{(q)}_1 - E^{(q)}_1) u_1.
\]

By construction of \( G_1 \) from \( \hat{G}_1 \), we have that \( (\text{Id} - \eta^{(q)}_2 R^{(q)}_2) (\hat{E}^{(q)}_1 - E^{(q)}_1) u_1 = 0 \), and \( R^{(q)}_2 (\hat{E}^{(q)}_1 - E^{(q)}_1) u_1 \in \hat{H}^m(\hat{\Omega}^{(q-1)}_{k_2}) \), and so
\[
(\hat{E}^{(q)}_1 - E^{(q)}_1) u_1 = \sum_{(\lambda,\bar{\lambda}) \in \nabla^{(q-1)}_{k_2}} (R^{(q)}_2 (\hat{E}^{(q)}_1 - E^{(q)}_1) u_1, \tilde{\psi}^{(q-1,k_2)}_{\lambda,\bar{\lambda}})_{L^2(\hat{\Omega}^{(q-1)}_{k_2})} \eta^{(q)}_2 \psi^{(q-1,k_2)}_{\lambda,\bar{\lambda}}.
\]
We set
\[ \hat{\nabla}_{k_2,M}^{(q-1)} := \{(\hat{\lambda}, \hat{p}) \in \nabla_{k_2}^{(q-1)} \subset (R_{k_2}^q(E_1^q - E_1^q)u_1, \psi_{\hat{\lambda},\hat{p}}^{(q-1,k_2)})_{L_2(\hat{\Omega}_{k_2}^{(q-1)})} \neq 0, \]
for some \( u_1 \in \exists P_{k_1,M}^{(q-1)} \).

Below we will show that, even after a possible enlargement to ensure the multiple tree property, it holds that \#\hat{\nabla}_{k_2,M}^{(q-1)} \lesssim \#\nabla_{k_1,M}^{(q-1)}\). Defining \( \nabla_{k,M}^{(q-1)} \) to be the union of \( \nabla_{k_2,M}^{(q-1)} \) and \( \nabla_{k_2,M}^{(q-1)} \), the proof is completed.

If \( (\hat{\lambda}, \hat{p}) \in \nabla_{k_2,M}^{(q-1)} \), then \( (R_{k_2}^q(E_1^q) \psi_{\hat{\lambda},\hat{p}}^{(q-1,k_2)}(q-1,k_2),_{L_2(\hat{\Omega}_{k_2}^{(q-1)})} \neq 0 \) for some \( (\lambda, p) \in \nabla_{k_1,M}^{(q-1)} \) with \( R_{k_2}^q(E_1^q) \psi_{\hat{\lambda},\hat{p}}^{(q-1,k_2)}(q-1,k_2) \), \( |E_1^q| \subset V_{|\lambda|+|M_{q-1}+L|e}(\hat{\Omega}_{k_2}^{(q-1)}) \). Using \( Z|\lambda|((\hat{\Omega}_{k_2}^{(q-1)}) \subset V_{|\lambda|+|M_{q-1}+L|e}(\hat{\Omega}_{k_2}^{(q-1)}) \) and the assumptions on the extension, we have
\[ R_{k_2}^q(E_1^q) \psi_{\hat{\lambda},\hat{p}}^{(q-1,k_2)} \in V_{|\lambda|+(M_{q-1}+L)e}(\hat{\Omega}_{k_2}^{(q-1)}) \subset Z|\lambda|+M_{q-1}+L)e(\hat{\Omega}_{k_2}^{(q-1)}) \]
and so \( |\hat{\lambda}| \leq |\lambda| + (M_{q-1} + m_{q-1} + L)e \). Here we applied both inclusions from Proposition 5.4(3).

Thanks to the multiple tree property of \( \nabla_{k_1,M}^{(q-1)} \), there exists a \( (\lambda', p') \in \nabla_{k_1,M}^{(q-1)} \) with \( |\lambda'| = \min(|\hat{\lambda}|, |\lambda|) \) \((1 \leq i \leq n) \) and \( \sup \psi_{\lambda',p'}^{(q-1,k_1)} \neq \emptyset \). Note that because of \( |\hat{\lambda}| \leq |\lambda| + (M_{q-1} + m_{q-1} + L)e \), we have \( |\lambda'| \leq |\lambda| + (M_{q-1} + m_{q-1} + L)e \).

The “localness” of \( \nabla_{k_1,M}^{(q-1)} \) as given by Proposition 5.4(1), the assumptions on the extension, and the “locally finiteness” of \( \hat{\nabla}_{k_2,M}^{(q-1)} \) as given by Proposition 5.4(2) show that the number of \( (\hat{\lambda}, \hat{p}) \in \hat{\nabla}_{k_2,M}^{(q-1)} \) with \( \hat{\nabla}_{k_2,M}^{(q-1)} \) on the same level \( |\hat{\lambda}| \leq |\hat{\lambda}| + (M_{q-1} + m_{q-1} + L)e \) is uniformly bounded. With this, we conclude that with the above mapping \( (\hat{\lambda}, \hat{p}) \mapsto (\lambda', p') \), an at most uniformly bounded number of \( (\hat{\lambda}, \hat{p}) \in \hat{\nabla}_{k_2,M}^{(q-1)} \) is mapped onto any \( (\lambda', p') \in \nabla_{k_1,M}^{(q-1)} \), and so that \#\hat{\nabla}_{k_2,M}^{(q-1)} \lesssim \#\nabla_{k_1,M}^{(q-1)}\).

Finally, to bound \#\hat{\nabla}_{k_2,M}^{(q-1)}\), we only used that for \( (\hat{\lambda}, \hat{p}) \in \hat{\nabla}_{k_2,M}^{(q-1)} \), there exists a \( (\lambda, p) \in \nabla_{k_1,M}^{(q-1)} \), with \( \sup \psi_{\lambda',p'}^{(q-1,k_1)} \neq \emptyset \) and \( |\hat{\lambda}| \leq |\lambda| + (M_{q-1} + m_{q-1} + L)e \). The same proof would have applied with the condition about the non-empty intersection of the supports reading as the condition that \( \sup \psi_{\lambda',p'}^{(q-1,k_1)} \) has non-empty intersection with some hyperrectangle, containing \( \psi_{\hat{\lambda},\hat{p}}^{(q-1,k_1)} \), that is aligned with the Cartesian coordinates with sides of lengths of order \( 2^{-|\hat{\lambda}|} \), \( \ldots, 2^{-|\hat{\lambda}|} \). In view of this, if \( \hat{\nabla}_{k_2,M}^{(q-1)} \) does not already have the multiple tree property, then it can be enlarged to have this property while retaining \#\hat{\nabla}_{k_2,M}^{(q-1)} \lesssim \#\nabla_{k_1,M}^{(q-1)}\).

6. Regularity

We study the issue whether we may expect (5.1) for \( u \) being the solution of an elliptic boundary value problem of order \( 2m = 2 \).

6.1. Two-dimensional case. Let \( \Omega \) be a polygonal domain. This means that its boundary is the union of a finite number of line segments, known as edges, with ends known as corners. It is not assumed that \( \Omega \) is a Lipschitz domain, so it may
contain cracks. We denote with \( \mathcal{E} \) the set of edges, with \( \mathcal{C} \) the set of corners, and set for \( c \in \mathcal{C} \),

\[
r_c(x) := \text{dist}(x, c).
\]

Following [CDN10], for \( m \in \mathbb{N}_0 \), we define the (non-homogeneous) weighted Sobolev space \( J_\beta^n(\Omega) \) as the set of \( u \in L^2_\text{loc}(\Omega) \) that have a finite squared norm

\[
\|v\|_{J_\beta^n(\Omega)}^2 := \sum_{k=0}^m \sum_{|\alpha| = k} \|\prod_{c \in \mathcal{C}} r_c^{\beta+m} \partial^\alpha v\|_{L^2(\Omega)}^2.
\]

(in [CDN10] the generalization is considered of \( \beta \) being possibly dependent on \( c \)).

Let \( A \) be a constant, real, symmetric and positive definite \( 2 \times 2 \) matrix. Let \( \mathcal{E}_D \subset \mathcal{E} \), and

\[
V(\Omega) := \begin{cases} \{v \in H^1(\Omega) : v|_e = 0 \ \forall e \in \mathcal{E}_D\} & \text{when } \mathcal{E}_D \neq \emptyset, \\
\{v \in H^1(\Omega) : \int_\Omega v \, dx = 0\} & \text{otherwise}.
\end{cases}
\]

Given \( g \in V(\Omega)' \), let \( u \in V(\Omega) \) denote the solution of

\[
(6.1) \quad \int_\Omega A \nabla u \cdot \nabla v \, dx = g(v) \quad (v \in V(\Omega)).
\]

**Theorem 6.1.** For \( m \in \mathbb{N}_0 \), there exists a \( b^* \in (0, m+2] \) such that for any \( b \in [0, b^*) \), the mapping \( g \mapsto u \in B(J_{-b+1}^m(\Omega), J_b^{m+2}(\Omega)) \).

The proof follows from [CDN10, formula (6.7)]. As stated in [CDN10, Example 6.7], for \( m \) sufficiently large, \( b^* > \frac{1}{2} \).

We refer to [CDN10, Sect. 7] for generalizations of Theorem 6.1 to differential operators with variable coefficients and/or lower order terms.

Concerning the smoothness condition on the right-hand side \( g \), note that for \( b \leq m + 1 \),

\[
H^m(\Omega) \hookrightarrow J_{-b+1}^m(\Omega).
\]

Let us now consider the situation that \( \Omega = \cup_{i=1}^K \Omega_i \) is an essentially disjoint subdivision into subdomains, where \( \Omega_i = \kappa_i(\square) \) with \( \kappa_i \) being a regular parametrization. Let \( R_i \) denote the restriction of functions on \( \Omega \) to \( \Omega_i \).

**Proposition 6.2.** If \( \kappa_i \in C^{m+2}(\square) \) and \( b \leq m + 1 \), then

\[
\kappa_i^* R_i \in B(J_{-b-1}^{m+2}(\Omega), J_{-b-1}^{m+2}(\square)).
\]

**Proof.** This follows from the smoothness of \( \kappa_i \), and from the fact that \( \kappa_i^* u|_{\Omega_i} \) localized near corners of \( \square \) that do not correspond to corners of \( \Omega \) is a function in \( H^{m+2} \hookrightarrow J_{-b-1}^{m+2} \), the latter by \( -b-1+m+2 \geq 0 \). \( \square \)

The following Proposition demonstrates (5.1).

**Proposition 6.3.** For \( d \in \mathbb{N}_0 \), \( \theta \geq \max(1, d-b/2) \), it holds that

\[
J^{2d}_{-b-1}(\square) \hookrightarrow \mathcal{H}^d_{0-1}(\mathcal{I}) \otimes \mathcal{H}^d_0(\mathcal{I}) \cap \mathcal{H}^d_{\theta}(\mathcal{I}) \otimes \mathcal{H}^d_{\theta-1}(\mathcal{I}) = \mathcal{H}^d_{1,\theta}(\square).
\]

**Proof.** This follows from \( \max(x^{\theta-1}y^{\theta}, x^{\theta}y^{\theta-1}) \leq r_0^{2\theta-1} \leq r_0^{2d-b-1} \) when \( r_0 \in [0, 1] \). \( \square \)
There exists an \( \varepsilon > 0 \) small enough such that if we set

\[
\begin{align*}
\Omega_e &:= \{ x \in \Omega : r_e(x) < \varepsilon, r_E(x) > r_e(x) (e \neq \hat{e} \in E), \text{ and } r_E(x) > \frac{\varepsilon}{2} \} \\
\Omega_c &:= \{ x \in \Omega : r_c(x) < \varepsilon \text{ and } r_E(x) > \frac{\varepsilon}{2} r_c(x) \} \\
\Omega_{ce} &:= \{ x \in \Omega : r_c(x) < \varepsilon \text{ and } r_e(x) < \varepsilon r_c(x) \} \\
\Omega_I &:= \{ x \in \Omega : r_E(x) > \frac{\varepsilon}{2} \}
\end{align*}
\]

we have the following properties

\[
\begin{align*}
\overline{\Omega_e} \cap \overline{\Omega_{e'}} &= \emptyset, \quad \overline{\Omega_{ce}} \cap \overline{\Omega_{ce'}} = \{ c \} \quad (e \neq e' \in E, c \in C), \\
\overline{B(c; \varepsilon)} \cap \overline{B(c'; \varepsilon)} &= \emptyset \quad (c \neq c' \in C), \quad \Omega = \Omega_I \cup \{ c \in C \} \cup \{ e \in E \} \cup \{ e \in C \} \cup \{ e \in C, e \in E \} \Omega_{ce}.
\end{align*}
\]

In a neighborhood of any edge \( e \in E \), we will take partial derivatives in an orthogonal coordinate system with one of the coordinate directions being parallel to \( e \). For a multi-index \( \alpha \) in that coordinate system, \( |\alpha_\perp| \) will denote the sum of the coordinates in the directions perpendicular to \( e \), and \( |\alpha_\parallel| := |\alpha| - |\alpha_\perp| \).

For \( m \in \mathbb{N}_0 \), \( \beta > -m \), and \( E_0 \subset E \), we define the \textit{anisotropic weighted Sobolev space}

\[
N^m_\beta(\Omega, C, E_0) := \left\{ u \in L^2_\text{loc}(\Omega) : \forall \alpha, |\alpha| \leq m, \partial^\alpha u \in L_2(\Omega) \right\},
\]

\[
\begin{align*}
r_e(x)^{\beta+|\alpha|} \partial^\alpha u &\in L_2(\Omega) \forall c \in C, \\
r_e(x)^{\beta+|\alpha_\perp|} \partial^\alpha u &\in L_2(\Omega) \forall e \in E_0, \\
r_e(x)^{\beta+|\alpha|} (r_e(x)/r_e(\tilde{x}))^{\beta+|\alpha_\perp|} \partial^\alpha u &\in L_2(\Omega_{ce}) \forall c \in C, e \in E_0 \\
r_e(x)^{\max(\beta+|\alpha_\perp|, 0)} \partial^\alpha u &\in L_2(\Omega) \forall e \in E \setminus E_0, \\
r_e(x)^{\beta+|\alpha|} (r_e(x)/r_e(\tilde{x}))^{\max(\beta+|\alpha_\perp|, 0)} \partial^\alpha u &\in L_2(\Omega_{ce}) \forall c \in C, e \in E \setminus E_0
\end{align*}
\]

with squared norm being the sum over \( |\alpha| \leq m \) of the squared \( L_2 \)-norms over \( \Omega_I \), \( \Omega_c \), \( \Omega_e \), and \( \Omega_{ce} \), respectively. (As in the two-dimensional case, this definition can be generalized to \( \beta \) being possibly dependent on \( c \) and \( e \).

The definition of \( N^m_\beta(\Omega, C, E_0) \) is a special case of a definition of \( N^m_\beta(\Omega, C_0, E_0) \) from [CDN10] for general \( C_0 \subset C \). In particular, the definition of the (fully) non-homogeneous anisotropic weighted Sobolev space \( N^m_\beta(\Omega, \emptyset, \emptyset) \) is obtained from (6.2) by taking \( E_0 = \emptyset \), and by replacing \( r_e(x)^{\beta+|\alpha|} \) by \( r_e(x)^{\max(\beta+|\alpha_\perp|, 0)} \) on all three occurrences. Obviously,

\[
N^m_\beta(\Omega, C, E_0) \hookrightarrow N^m_\beta(\Omega).
\]
Let $A$ be a constant, real, symmetric and positive definite $3 \times 3$ matrix. Let $\mathcal{F}_D \subset \mathcal{F}$, and

$$V(\Omega) := \begin{cases} \{ v \in H^1(\Omega) : v|_f = 0 \forall f \in \mathcal{F}_D \} & \text{when } \mathcal{F}_D \neq \emptyset, \\ \{ v \in H^1(\Omega) : \int_\Omega v \, dx = 0 \} & \text{otherwise.} \end{cases}$$

Given $g \in V(\Omega)'$, let $u \in V(\Omega)$ denote the solution of

$$(6.4) \quad \int_\Omega A \nabla u \cdot \nabla v \, dx = g(v) \quad (v \in V(\Omega)).$$

**Theorem 6.4.** Let $\mathcal{E}_0$ be the set of all $e \in \mathcal{E}$ that are an edge of an $f \in \mathcal{F}_D$. There exists a $b^* \in (0, 1]$ such that for $m \in \mathbb{N}$, $m > 1$, and for any $b \in [0, b^*)$, the mapping $g \mapsto u \in B(N_{1-b}^m(\Omega, C, \mathcal{E}_0), N_{1-b}^m(\Omega, C, \mathcal{E}_0))$.

Indeed, with the isotropic weighted Sobolev spaces $J^m_\beta(\Omega)$ as defined in [CDN10, Def. 5.9] (where we consider the value of $\beta$ to be independent of the edges and corners), [MR03, Th. 7.1] shows that $g \mapsto u \in B(J^0_{1-b}(\Omega), J^1_{1-b}(\Omega))$, and thus that $g \mapsto u \in B(J^0_{1-b}(\Omega), J^1_{1-b}(\Omega))$. Using that $N_{1-b}^m(\Omega, C, \mathcal{E}_0) \hookrightarrow J^0_{1-b}(\Omega)$, we conclude the statement of the theorem from the anisotropic regularity shift theorem [CDN10, (5.25)(a)]. Here we used that the Assumptions 5.5 and 5.13 from [CDN10] for $e \in \mathcal{E}_0$ or $e \in \mathcal{E} \setminus \mathcal{E}_0$, respectively, are satisfied by an application of [MR03, Th. 7.2].

Concerning the smoothness condition on the right-hand side $g$, note that for $b \leq 1$,

$$H^m(\Omega) \hookrightarrow N_{1-b}^m(\Omega, C, \mathcal{E}_0).$$

The fact, as proven in Thm. 6.4, that for sufficiently smooth right-hand side, the tangential derivatives of sufficiently high order along the edges of $\Omega$ of the solution of (6.4) are in the (unweighted) $L_2(\Omega)$ space, is essential for our goal of proving approximation rates with piecewise tensor product approximation as for one-dimensional problems.

Let us consider the situation that $\Omega = \bigcup_{i=1}^K \Omega_i$ is an essentially disjoint conforming subdivision into hexahedra that are images of $\square$ under trilinear diffeomorphisms $\kappa_i$, with $\inf_{x \in \square} |D\kappa_i(x)| > 0$.

Aiming at deriving a three dimensional analogue of Proposition 6.2, care has to be taken that for $\kappa_i^* R_i u$ to be in $N_{1-b}^m(\square)$, its tangential derivatives along an edge up to order $m$ have to be in $L_2(\square)$. Therefore, we have to ensure that if an edge of $\square$ is mapped onto the boundary of $\Omega$, then lines parallel to this edge are (smoothly) mapped onto lines parallel to the boundary of $\Omega$.

**Proposition 6.5.** Let for any $i$, $\kappa_i$ be such that if it maps an edge $e$ of $\square$ to an edge of $\Omega$, then it maps all three edges that are parallel to $e$ to edges that are parallel to $\kappa_i(e)$. Then

$$\kappa_i^* R_i \in B(N_{1-b}^m(\Omega), N_{1-b}^m(\square)).$$

**Proof.** What has to be shown is that if an edge $e$ of $\square$ is mapped to the boundary of $\Omega$, then the tangential derivatives along $e$ of $u \circ \kappa_i$ up to order $m$ are smooth functions of the tangential derivatives of $u$ along $\kappa_i(e)$ up to order $m$.

W.l.o.g., let $e$ be one of the edges $e^{(1)}, \ldots, e^{(4)}$ that are parallel to the first unit vector. The vector $\partial_1 \kappa_i(x)$ is a bilinear function of $x_2$ and $x_3$, and so in particular constant on each of the $e^{(j)}$. These constant vectors are the differences of the
endpoints of $\kappa_i(e^{(j)})$, and so, by assumption, multiples of $\partial_1\kappa_i|_e$. We conclude that $\partial_1\kappa_i(x)$ is a multiple of a bilinear scalar function and $\partial_1\kappa_i|_e$. □

Next we will show that the condition on the parametrizations imposed in Proposition 6.5 can always be satisfied by making some refinement of the initial conforming subdivision into hexahedra: Let us cut each hexahedron in the partition along 6 planes parallel to the 6 faces of the hexahedron on distance $\zeta > 0$, see Figure 5. When $\zeta$ is small enough, then the planes parallel to opposite faces of the hexahedron do not intersect inside the hexahedron, and we obtain a subdivision of the hexahedron in $3^3$ subhexahedra. Eight of these subhexahedra share a corner with the original hexahedron and so have three edges on edges of this hexahedron, and so possibly three edges on edges of $\Omega$. These subhexahedra are parallelepipeds and so satisfy the condition from Proposition 6.5. Twelve other subhexahedra have one edge on an edge of the original hexahedron, and so possibly on an edge of $\Omega$. For each of these subhexahedra, the edges opposite to this specific edge are parallel to this edge and so satisfy the condition from Proposition 6.5. The remaining seven subhexahedra have no edges on edges of the original hexahedron, and thus no edge on an edge of $\Omega$. Six of them have a face on a face of the original hexahedron, whereas the boundary of the remaining “interior” hexahedron has empty intersection with the boundary of the original hexahedron.

Above subdivision of a hexahedron induces a subdivision of each of its faces into $3^2$ quadrilaterals; 4 parallelograms at the corners, 4 trapezoids at the edges, and one interior quadrilateral. Conversely, such a subdivision of 3 non-opposite faces of the hexahedron, where the interior quadrilaterals are sufficiently large, determines uniquely the subdivision of the hexahedron into $3^3$ subhexahedra by making cuts along planes parallel to the faces. So if we start with a subdivision of one hexahedron and use the resulting subdivision of its faces to induce subdivisions of its neighbors, then by choosing $\zeta$ small enough we obtain a refinement of the original conforming decomposition into hexahedra to a conforming decomposition into hexahedra that satisfy the conditions needed for Proposition 6.5.

What is left to show is whether the subhexahedra in the refined subdivision are images of $\square$ under trilinear diffeomorphisms $\kappa_i$, with $\inf_{x \in \square} |D\kappa_i(x)| > 0$. When the aforementioned parameter $\zeta$ tends to zero, the interior hexahedron converges
to the hexahedron in the original decomposition, which was assumed to have this property. So for \( \zeta \) small enough, the interior hexahedra have this property.

The other hexahedra in the refined subdivision have at least two parallel faces, and so are instances of a prismatoid. Let us consider such a hexahedron with its parallel faces, being convex quadrilaterals, on the planes \( z = 0 \) and \( z = 1 \). Let \( q_1, q_2 : (0, 1)^2 \to \mathbb{R}^3 \) be bilinear parametrizations of the bottom and top face with

\[
\inf_{(x,y) \in (0,1)^2} |Dq_1(x,y)| > 0, \quad \text{and such that the images of each corner of } (0, 1)^2 \text{ under } q_1 \text{ and } q_2 \text{ are connected by an edge in the hexahedron.}
\]

Then a trilinear parametrization \( \square \to \mathbb{R}^3 \) is given by

\[
\kappa(x,y,z) = (1 - z)q_1(x,y) + zq_2(x,y)
\]

and so \( \inf_{(x,y,z) \in \square} |D\kappa(x,y,z)| = \inf_{(x,y,z) \in (1 - z)|Dq_1(x,y)| + z|Dq_2(x,y)| > 0. \)

The following Proposition demonstrates (5.1).

**Proposition 6.6.** For \( d \in \mathbb{N}_0, \theta \geq \max(1, d - \frac{b}{3}) \) where \( b > 0 \), it holds that

\[
N_{3d - b}(\square) \subseteq \mathcal{H}_{d, \theta}^d(\square).
\]

**Proof.** It is sufficient to show continuity of the embedding of the spaces restricted to \( \Omega_e, \Omega_e, \) and \( \Omega_{ce} \) intersected with \((0, \frac{1}{2})^3\), where \( e = (0,0,0) \) and \( e = e_1 \).

For \( \| \alpha \|_\infty \leq d \), the conditions on \( \theta \) show that on \( \Omega_e \cap (0, \frac{1}{2})^3 \),

\[
\max(x^{\theta_1}y^{\theta_2}z^{\theta_3}, x^{\theta_2}y^{\theta_1}z^{\theta_3}, x^{\theta_3}y^{\theta_1}z^{\theta_3}, x^{\theta_1}y^{\theta_2}z^{\theta_3}) \leq r_e(x)^{3\theta - 1} \leq r_e(x)^{\max(-1-b+|\alpha|,0)},
\]

and on \( \Omega_{ce} \cap (0, \frac{1}{2})^3 \),

\[
\max(y^{\theta_1}z^{\theta_2}, y^{\theta_2}z^{\theta_1}, y^{\theta_1}z^{\theta_2}) \leq r_e(x)^{2\theta - 1} \leq r_e(x)^{\max(-1-b+\alpha_2+\alpha_3,0)}.
\]

On \( \Omega_{ce} \cap (0, \frac{1}{2})^3 \), we have

\[
\max(x^{\theta_1}y^{\theta_2}z^{\theta_3}, x^{\theta_2}y^{\theta_1}z^{\theta_3}, x^{\theta_3}y^{\theta_1}z^{\theta_3}) \leq r_e(x)^{\theta_1}r_e(x)^{\theta_2}r_e(x)^{2\theta - 1}.
\]

To show that this right-hand side can be bounded on

\[
r_e(x)^{\max(-1-b+|\alpha|,0)-\max(-1-b+\alpha_2+\alpha_3,0)}r_e(x)^{\max(-1-b+\alpha_2+\alpha_3,0)}
\]

we distinguish between 3 cases: For \(-1-b+|\alpha| \leq 0 \), this results from \( \theta \geq 0 \) and \( 2\theta - 1 \geq 0 \). For \(-1-b+|\alpha| \geq 0 \geq -1-b+\alpha_2+\alpha_3 \), we have

\[
r_e(x)^{\theta_1}r_e(x)^{\theta_2}r_e(x)^{2\theta - 1} \leq r_e(x)^{\theta_1}r_e(x)^{\theta_2} \leq r_e(x)^{\theta_1} \leq r_e(x)^{-1-b+\alpha_2+\alpha_3} \leq r_e(x)^{-1-b+\alpha_2+\alpha_3} \leq r_e(x)^{-1-b+\alpha_2+\alpha_3} \leq r_e(x)^{-1-b+\alpha_2+\alpha_3} \leq r_e(x)^{-b+\theta_{\alpha}}r_e(x)^{2\theta - 1} \leq r_e(x)^{\alpha_1}r_e(x)^{-1-b+\alpha_2+\alpha_3} \leq r_e(x)^{-b+\theta_{\alpha}} \leq r_e(x)^{-b+\theta_{\alpha}}.
\]

**7. Numerical results**

As the univariate building block of the piecewise tensor product wavelet construction, we apply the \( C^1 \), piecewise quartic (so \( d = 5 \)) (multi-) wavelets, with (discontinuous) piecewise quartic duals as constructed in [CS11]. The primal wavelets satisfy Dirichlet boundary conditions of order 1 at both boundaries 0 and 1, i.e.,

\[
\tilde{\sigma} = (\sigma_l, \sigma_r) = (1,1), \text{ whereas at the dual side no boundary conditions can be imposed, i.e., } \tilde{\sigma} = (\tilde{\sigma}_l, \tilde{\sigma}_r) = (0,0).
\]

For the present work, we generalized this construction to obtain also wavelet collections that satisfy no boundary conditions (at primal side) at either or both boundaries, i.e., \( \tilde{\sigma} \in \{0,1\}^2 \setminus \{(1,1)\} \). Actually, we also slightly modified the biorthogonal collections \( (\Psi_{(1,1),(0,0)}, \tilde{\Psi}_{(1,1),(0,0)}) \) from [CS11] with the aim to minimize, for \( \tilde{\sigma} \in \{0,1\}^2 \setminus \{(1,1)\} \), the number of \( \lambda \in \nabla_{\tilde{\sigma},(0,0)} \) for which either
dual wavelets by an application of Proposition 5.2. Indeed, recall from Remark 5.3 that the extension operator has to be applied to all primal wavelets with such indices $\lambda$ (at either left or right boundary). We obtained the result that the number of such $\lambda$ on each level at left or right boundary is equal to 2. One of them corresponds to a primal wavelet that does not vanish at the boundary and therefore has to be extended to obtain a continuous extension, whereas the primal wavelet corresponding to the other only has to be extended to guarantee locality of the resulting dual wavelets by an application of Proposition 5.2.

As extension operator, we apply the simple reflection suited for $0 < \lambda < \frac{3}{2}$.

As domains, we consider the 2-dimensional slit domain $\Omega = (0, 2)^2 \setminus \{1\} \times [1, 2]$, being the union of 4 squares from $\mathbb{Z}^2 + (0, 1)^2$, and the 3-dimensional L-shaped domain $\Omega = (0, 2) \times (0, 2) \times (0, 1) \setminus (1, 2) \times (1, 2) \times (0, 1)$, being the union of 3 cubes from $\mathbb{Z}^3 + (0, 1)^3$. Aiming at constructing Riesz bases for $[H^s(\Omega), H^s_0(\Omega)]_{s,2}$ ($s \in [0, 1]$), in particular for $H^s_0(\Omega)$, we impose homogeneous Dirichlet boundary conditions of order 1 at $\partial \Omega$.

In the slit domain case, we consider tensor product wavelet bases on the squares $(0, 1)^2$, $\{(1, 0)\} + (0, 1)^2$ with no boundary conditions on the left edge, and $\{(0, 1)\} + (0, 1)^2$ with no boundary conditions on their bottom edge, with homogeneous Dirichlet boundary conditions of order 1 on all other edges. By applying the scale-dependent extension, first from $\{(0, 1)\} + (0, 1)^2$ to $(0, 2) \times (0, 1)$, and then from both top domains $\{(0, 1)\} + (0, 1)^2$ and $\{(1, 1)\} + (0, 1)^2$ over their bottom edges to $\Omega$, we end up with the piecewise tensor product basis.

In the L-shaped domain case, we consider tensor product wavelet bases on the cubes $(0, 1)^3$, and $\{(1, 0, 0)\} + (0, 1)^3$ and $\{(0, 1, 0)\} + (0, 1)^3$ with no boundary conditions on their interface with $(0, 1)^3$, with homogeneous Dirichlet boundary conditions of order 1 on all other faces. By applying the scale-dependent extension from $\{(1, 0, 0)\} + (0, 1)^3$ to $(0, 2) \times (0, 1)^2$, and then from $\{(0, 1, 0)\} + (0, 1)^3$ to $\Omega$, the piecewise tensor product basis is obtained.

Using these piecewise tensor product bases, we solved the Poisson problem of finding $u \in H^1_0(\Omega)$ such that

$$\int_{\Omega} \nabla u \cdot \nabla v = f(v) \quad (v \in H^1_0(\Omega))$$

by applying the adaptive wavelet-Galerkin method ([CDD01, Ste09]). This method is known to produce a sequence of approximations from the span of the basis that converge in $H^1(\Omega)$-norm with the best possible rate. Assuming a sufficiently smooth right-hand side, Theorem 5.6 together with the regularity results from §6.1 or §6.2 show that this rate is $d - m = 5 - 1 = 4$ (indeed an even higher rate can generally not be expected).

Furthermore, if the bi-infinite stiffness matrix of the PDE w.r.t. the basis is sufficiently close to a sparse matrix, in the sense that it is $s^*$-compressible for some $s^* > 4$, then this adaptive method has optimal computational complexity. The univariate wavelet basis from [CS11] was designed such that any second order PDE on $(0, 1)^n$ with homogeneous Dirichlet boundary conditions gives rise, w.r.t. the tensor product basis, to a bi-infinite stiffness matrix which is truly sparse.
that columns corresponding to wavelets that are not zero at an interface contain infinitely many non-zero entries. The sizes of these entries, however, decay that fast as function of the difference in levels of the wavelets involved that nevertheless the stiffness matrix is $s^*$-compressible with $s^* = \infty$, meaning that indeed the adaptive method has optimal computational complexity.

To investigate how the application of the extensions, and the incorporation of wavelets with other boundary conditions, affects the conditioning of the bi-infinite stiffness matrix, we computed numerically the condition number of the stiffness matrix ("preconditioned" by its diagonal) w.r.t. the piecewise tensor product wavelet basis on the slit domain, as well as that corresponding to the Poisson problem on $(0,1)^2$ with the tensor product wavelet basis (with homogeneous Dirichlet boundary conditions). The results are given in Table 1.

**Table 1.** Condition numbers of the diagonally preconditioned stiffness matrix on $(0,1)^2$ with tensor product basis, and that on the slit domain $(0,2)^2 \setminus \{1\} \times [1,2]$ with piecewise tensor product basis. The bi-infinite stiffness matrices are restricted to the square block corresponding to row and column indices $\lambda$ with $||\lambda||_{\infty} \leq J$. The cardinality of this set of row- or column-indices is (approximately) equal to $(3.2^{J+1})^2$ or $4.(3.2^{J+1})^2$, respectively.

We consider the Poisson problem on the slit domain for right-hand side $f = 1$. Its solution is illustrated in Figure 6. In Figure 7 we give the support lengths, in piecewise tensor product wavelet coordinates, of the approximate solutions obtained by the adaptive wavelet-Galerkin scheme vs. the (relative) $\ell_2$-norm of their residual in the bi-infinite matrix vector system, the latter being equivalent to the $H^1(\Omega)$-norm of the error. The optimal rate -4 indicated by the slope of the hypotenuse of the triangle is accurately approached for the problems sizes near the end of the computation. The centers of supports of the piecewise tensor product wavelets that were selected by the adaptive wavelet-Galerkin scheme are indicated Figure 8.

...
Figure 7: Support length vs. relative residual of the approximations produced by the adaptive wavelet-Galerkin scheme for the Poisson problem on the slit domain \((0, 2)^2 \setminus \{1\} \times [1, 2]\) with right-hand side \(f = 1\) and the piecewise tensor product basis.

Figure 8: Centers of the supports of the piecewise tensor product wavelets that were selected by the adaptive wavelet-Galerkin scheme. The right picture is a zoom in of the left one.

Next we give numerical results for the Poisson problem on the L-shaped domain \(\Omega = (0, 2) \times (0, 2) \times (0, 1) \setminus (1, 2) \times (1, 2) \times (0, 1)\) with right-hand side \(f(x, y, z) = x(x - 2)y(y - 2)z\). In Figure 9 we give the support lengths, in piecewise tensor product wavelet coordinates, of the approximate solutions obtained by the adaptive wavelet-Galerkin scheme vs. the (relative) \(\ell_2\)-norm of their residual in the bi-infinite matrix vector system, the latter being equivalent to the \(H^1(\Omega)\)-norm of the error. With the maximum problem size \(\approx 2.10^5\) that we could reach on our PC, the rate is still not very close to the asymptotic rate \(-4\). We expect that this is caused by the combination of a strong singularity in the solution, a three-dimensional domain, and the application of (piecewise) tensor product approximation. Indeed, although the asymptotic rate is independent of the spatial dimension, it is generally observed that with tensor product approximation in higher dimensions it takes an increasingly longer time before this rate becomes visible. Note that a rate \(-4\) in
the $H^1(\Omega)$-norm with an isotropic method would require approximation of order 13, if already attainable at all in view of regularity constraints.

Figure 9. Support length vs. relative residual of the approximations produced by the adaptive wavelet-Galerkin scheme for the Poisson problem on the slit domain L-shaped domain $\Omega = (0,2) \times (0,2) \times (0,1) \setminus (1,2) \times (1,2) \times (0,1)$ with right-hand side $f(x,y,z) = x(x - 2)y(y - 2)z$ and the piecewise tensor product basis.

The centers of supports of the piecewise tensor product wavelets that were selected by the adaptive wavelet-Galerkin scheme are indicated in Figure 10.
